# Preface

This guide provides reference information for Greenplum Database.

- [About This Guide](#)
- [Document Conventions](#)
- [Getting Support](#)

---

## About This Guide

This guide provides reference information for a Greenplum Database system. This guide is intended for system and database administrators responsible for managing a Greenplum Database system.

This guide assumes knowledge of Linux/UNIX system administration, database management systems, database administration, and structured query language (SQL).

Because Greenplum Database is based on PostgreSQL 8.2.15, this guide assumes some familiarity with PostgreSQL. References to [PostgreSQL documentation](#) are provided throughout this guide for features that are similar to those in Greenplum Database.

This guide contains the following reference documentation:

- [SQL Command Reference](#)
- [SQL 2008 Optional Feature Compliance](#)
- [System Catalog Reference](#)
- [Greenplum Environment Variables](#)
- [The gp\\_toolkit Administrative Schema](#)
- [Greenplum Database Data Types](#)
- [Character Set Support](#)
- [Server Configuration Parameters](#)
- [Greenplum MapReduce Specification](#)
- [Greenplum PostGIS Extension](#)
- [Summary of Greenplum Features](#)

## About the Greenplum Database Documentation Set

The Greenplum Database 4.3 documentation set consists of the following guides.

**Table 1** Greenplum Database documentation set

Guide Name	Description
Greenplum Database Database Administrator Guide	Every day DBA tasks such as configuring access control and workload management, writing queries, managing data, defining database objects, and performance troubleshooting.
Greenplum Database System Administrator Guide	Describes the Greenplum Database architecture and concepts such as parallel processing, and system administration tasks for Greenplum Database such as configuring the server, monitoring system activity, enabling high-availability, backing up and restoring databases, and expanding the system.
Greenplum Database Reference Guide	Reference information for Greenplum Database systems: SQL commands, system catalogs, environment variables, character set support, datatypes, the Greenplum MapReduce specification, postGIS extension, server parameters, the gp_toolkit administrative schema, and SQL 2008 support.
Greenplum Database Utility Guide	Reference information for command-line utilities, client programs, and Oracle compatibility functions.
Greenplum Database Installation Guide	Information and instructions for installing and initializing a Greenplum Database system.

## Document Conventions

The following conventions are used throughout the Greenplum Database documentation to help you identify certain types of information.

- [Text Conventions](#)
- [Command Syntax Conventions](#)

### Text Conventions

**Table 2** Text Conventions

Text Convention	Usage	Examples
<b>bold</b>	Button, menu, tab, page, and field names in GUI applications	Click <b>Cancel</b> to exit the page without saving your changes.
<i>italics</i>	New terms where they are defined Database objects, such as schema, table, or columns names	The <i>master instance</i> is the postgres process that accepts client connections.  Catalog information for Greenplum Database resides in the <i>pg_catalog</i> schema.

**Table 2** Text Conventions

Text Convention	Usage	Examples
<code>monospace</code>	File names and path names Programs and executables Command names and syntax Parameter names	Edit the <code>postgresql.conf</code> file.  Use <code>gpstart</code> to start Greenplum Database.
<code>monospace italics</code>	Variable information within file paths and file names  Variable information within command syntax	<code>/home/gpadmin/config_file</code>  <code>COPY tablename FROM 'filename'</code>
<b><code>monospace bold</code></b>	Used to call attention to a particular part of a command, parameter, or code snippet.	Change the host name, port, and database name in the JDBC connection URL:  <code>jdbc:postgresql://<b>host:5432/m</b> <b>ydb</b></code>
UPPERCASE	Environment variables  SQL commands  Keyboard keys	Make sure that the Java <code>/bin</code> directory is in your <code>\$PATH</code> .  <code>SELECT * FROM my_table;</code>  Press <code>CTRL+C</code> to escape.

---

## Command Syntax Conventions

**Table 3** Command Syntax Conventions

Text Convention	Usage	Examples
<code>{ }</code>	Within command syntax, curly braces group related command options. Do not type the curly braces.	<code>FROM { 'filename'   STDIN }</code>
<code>[ ]</code>	Within command syntax, square brackets denote optional arguments. Do not type the brackets.	<code>TRUNCATE [ TABLE ] name</code>
<code>...</code>	Within command syntax, an ellipsis denotes repetition of a command, variable, or option. Do not type the ellipsis.	<code>DROP TABLE name [, ...]</code>

**Table 3** Command Syntax Conventions

Text Convention	Usage	Examples
	Within command syntax, the pipe symbol denotes an “OR” relationship. Do not type the pipe symbol.	VACUUM [ FULL   FREEZE ]
\$ <i>system_command</i> # <i>root_system_command</i> => <i>gpdb_command</i> =# <i>su_gpdb_command</i>	Denotes a command prompt - do not type the prompt symbol. \$ and # denote terminal command prompts. => and =# denote Greenplum Database interactive program command prompts (psql or gpssh, for example).	\$ createdb mydatabase # chown gpadmin -R /datadir => SELECT * FROM mytable; =# SELECT * FROM pg_database;

---

## Getting Support

EMC support, product, and licensing information can be obtained as follows.

---

### Product information

For product-specific documentation, release notes, or software updates, go to the EMC Online Support site at [support.emc.com](http://support.emc.com).

For information about EMC products, licensing, and service, go to the EMC Powerlink website (registration required) at <http://Powerlink.EMC.com>.

---

### Technical support

For technical support, go to [EMC Online Support](http://support.emc.com). On the Support page, you will see several options, including one for making a service request. Note that to open a service request, you must have a valid support agreement. Please contact your EMC sales representative for details about obtaining a valid support agreement or with questions about your account.

# 1. SQL Command Reference

The following SQL commands are available in Greenplum Database:

- `ABORT`
- `ALTER AGGREGATE`
- `ALTER CONVERSION`
- `ALTER DATABASE`
- `ALTER DOMAIN`
- `ALTER EXTERNAL TABLE`
- `ALTER FILESPACE`
- `ALTER FOREIGN DATA WRAPPER*`
- `ALTER FOREIGN TABLE*`
- `ALTER FUNCTION`
- `ALTER GROUP`
- `ALTER INDEX`
- `ALTER LANGUAGE`
- `ALTER OPERATOR`
- `ALTER OPERATOR CLASS`
- `ALTER PROTOCOL`
- `ALTER RESOURCE QUEUE`
- `ALTER ROLE`
- `ALTER SCHEMA`
- `ALTER SEQUENCE`
- `ALTER SERVER*`

## SQL Syntax Summary

### ABORT

Aborts the current transaction.

```
ABORT [WORK | TRANSACTION]
```

### ALTER AGGREGATE

Changes the definition of an aggregate function

```
ALTER AGGREGATE name ( type [ , ... ] ) RENAME TO new_name
ALTER AGGREGATE name ( type [ , ... ] ) OWNER TO new_owner
ALTER AGGREGATE name ( type [ , ... ] ) SET SCHEMA new_schema
```

### ALTER CONVERSION

Changes the definition of a conversion.

```
ALTER CONVERSION name RENAME TO newname
ALTER CONVERSION name OWNER TO newowner
```

### ALTER DATABASE

Changes the attributes of a database.

```
ALTER DATABASE name [ WITH CONNECTION LIMIT conlimit ]
ALTER DATABASE name SET parameter { TO | = } { value | DEFAULT }
ALTER DATABASE name RESET parameter
ALTER DATABASE name RENAME TO newname
ALTER DATABASE name OWNER TO new_owner
```

### ALTER DOMAIN

Changes the definition of a domain.

```
ALTER DOMAIN name { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name { SET | DROP } NOT NULL
ALTER DOMAIN name ADD domain_constraint
ALTER DOMAIN name DROP CONSTRAINT constraint_name [RESTRICT | CASCADE]
ALTER DOMAIN name OWNER TO new_owner
ALTER DOMAIN name SET SCHEMA new_schema
```

### ALTER EXTERNAL TABLE

Changes the definition of an external table.

```
ALTER EXTERNAL TABLE name RENAME [COLUMN] column TO new_column
ALTER EXTERNAL TABLE name RENAME TO new_name
ALTER EXTERNAL TABLE name SET SCHEMA new_schema
ALTER EXTERNAL TABLE name action [, ... ]
```

where *action* is one of:

```
ADD [COLUMN] column_name type
DROP [COLUMN] column
ALTER [COLUMN] column TYPE type [USING expression]
OWNER TO new_owner
```

**ALTER FILESPACE**

Changes the definition of a filesystem.

```
ALTER FILESPACE name RENAME TO newname
```

```
ALTER FILESPACE name OWNER TO newowner
```

**ALTER FUNCTION**

Changes the definition of a function.

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] ) action [, ... ]  
[RESTRICT]
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] ) RENAME TO new_name
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] ) OWNER TO new_owner
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] ) SET SCHEMA  
new_schema
```

where *action* is one of:

```
{ CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
```

```
{ IMMUTABLE | STABLE | VOLATILE }
```

```
{ [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
```

**ALTER GROUP**

Changes a role name or membership.

```
ALTER GROUP groupname ADD USER username [, ... ]
```

```
ALTER GROUP groupname DROP USER username [, ... ]
```

```
ALTER GROUP groupname RENAME TO newname
```

**ALTER INDEX**

Changes the definition of an index.

```
ALTER INDEX name RENAME TO new_name
```

```
ALTER INDEX name SET TABLESPACE tablespace_name
```

```
ALTER INDEX name SET ( FILLFACTOR = value )
```

```
ALTER INDEX name RESET ( FILLFACTOR )
```

**ALTER LANGUAGE**

Changes the name of a procedural language.

```
ALTER LANGUAGE name RENAME TO newname
```

**ALTER OPERATOR**

Changes the definition of an operator.

```
ALTER OPERATOR name ( {lefttype | NONE} , {righttype | NONE} ) OWNER TO newowner
```

**ALTER OPERATOR CLASS**

Changes the definition of an operator class.

```
ALTER OPERATOR CLASS name USING index_method RENAME TO newname
```

```
ALTER OPERATOR CLASS name USING index_method OWNER TO newowner
```

**ALTER PROTOCOL**

Changes the definition of a protocol.

```
ALTER PROTOCOL name RENAME TO newname
```

```
ALTER PROTOCOL name OWNER TO newowner
```

**ALTER RESOURCE QUEUE**

Changes the limits of a resource queue.

```
ALTER RESOURCE QUEUE name WITH ( queue_attribute=value [, ... ] )
```

where *queue\_attribute* is:

```
    ACTIVE_STATEMENTS=integer
    MEMORY_LIMIT='memory_units'
    MAX_COST=float
    COST_OVERCOMMIT={TRUE|FALSE}
    MIN_COST=float
    PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}
```

```
ALTER RESOURCE QUEUE name WITHOUT ( queue_attribute [, ... ] )
```

where *queue\_attribute* is:

```
    ACTIVE_STATEMENTS
    MEMORY_LIMIT
    MAX_COST
    COST_OVERCOMMIT
    MIN_COST
```

**ALTER ROLE**

Changes a database role (user or group).

```
ALTER ROLE name RENAME TO newname
```

```
ALTER ROLE name SET config_parameter {TO | =} {value | DEFAULT}
```

```
ALTER ROLE name RESET config_parameter
```

```
ALTER ROLE name RESOURCE QUEUE {queue_name | NONE}
```

```
ALTER ROLE name [ [WITH] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEEXTTABLE | NOCREATEEXTTABLE
| [ ( attribute='value'[, ...] ) ]
    where attributes and values are:
        type='readable'|'writable'
        protocol='gpfdist'|'http'
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| CONNECTION LIMIT conlimit
| [ENCRYPTED | UNENCRYPTED] PASSWORD 'password'
| VALID UNTIL 'timestamp'
| [ DENY deny_point ]
| [ DENY BETWEEN deny_point AND deny_point]
| [ DROP DENY FOR deny_point ]
```

## ALTER SCHEMA

Changes the definition of a schema.

```
ALTER SCHEMA name RENAME TO newname
```

```
ALTER SCHEMA name OWNER TO newowner
```

## ALTER SEQUENCE

Changes the definition of a sequence generator.

```
ALTER SEQUENCE name [INCREMENT [ BY ] increment]  
    [MINVALUE minvalue | NO MINVALUE]  
    [MAXVALUE maxvalue | NO MAXVALUE]  
    [RESTART [ WITH ] start]  
    [CACHE cache] [[ NO ] CYCLE]  
    [OWNED BY {table.column | NONE}]  
  
ALTER SEQUENCE name SET SCHEMA new_schema
```

**ALTER TABLE**

Changes the definition of a table.

```
ALTER TABLE [ONLY] name RENAME [COLUMN] column TO new_column
```

```
ALTER TABLE name RENAME TO new_name
```

```
ALTER TABLE name SET SCHEMA new_schema
```

```
ALTER TABLE [ONLY] name SET
    DISTRIBUTED BY (column, [ ... ] )
| DISTRIBUTED RANDOMLY
| WITH (REORGANIZE=true|false)
```

```
ALTER TABLE [ONLY] name action [, ... ]
```

```
ALTER TABLE name
    [ ALTER PARTITION { partition_name | FOR (RANK(number))
                        | FOR (value) } partition_action [...] ]
    partition_action
```

where *action* is one of:

```
ADD [COLUMN] column_name type
    [ ENCODING ( storage_directive [,...] ) ]
    [column_constraint [ ... ]]
DROP [COLUMN] column [RESTRICT | CASCADE]
ALTER [COLUMN] column TYPE type [USING expression]
ALTER [COLUMN] column SET DEFAULT expression
ALTER [COLUMN] column DROP DEFAULT
ALTER [COLUMN] column { SET | DROP } NOT NULL
ALTER [COLUMN] column SET STATISTICS integer
ADD table_constraint

[ WITH ( partition_storage_parameter=value [, ...] ) ]
[ TABLESPACE tablespace ]

```

where *subpartition\_spec* is:

*subpartition\_element* [, ...]

and *subpartition\_element* is:

```

DEFAULT SUBPARTITION subpartition_name
| [SUBPARTITION subpartition_name] VALUES (list_value [, ...] )
| [SUBPARTITION subpartition_name]
  START ([datatype] 'start_value') [INCLUSIVE | EXCLUSIVE]
  [ END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE] ]
  [ EVERY ( [number / datatype] 'interval_value') ]
| [SUBPARTITION subpartition_name]
  END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE]
  [ EVERY ( [number / datatype] 'interval_value') ]
[ WITH ( partition_storage_parameter=value [, ...] ) ]
[ TABLESPACE tablespace ]

```

where *storage\_parameter* is:

```

APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
COMPRESSLEVEL={0-9}
FILLFACTOR={10-100}
OIDS[=TRUE|FALSE]

```

where *storage\_directive* is:

```

COMPRESSTYPE={ZLIB | QUICKLZ | RLE_TYPE | NONE}
| COMPRESSLEVEL={0-9}
| BLOCKSIZE={8192-2097152}

```

Where *column\_reference\_storage\_directive* is:

```

COLUMN column_name ENCODING (storage_directive [, ...] ), ...
|
DEFAULT COLUMN ENCODING (storage_directive [, ...] )

```

**ALTER TABLESPACE**

Changes the definition of a tablespace.

```
ALTER TABLESPACE name RENAME TO newname
```

```
ALTER TABLESPACE name OWNER TO newowner
```

**ALTER TRIGGER**

Changes the definition of a trigger.

```
ALTER TRIGGER name ON table RENAME TO newname
```

**ALTER TYPE**

Changes the definition of a data type.

```
ALTER TYPE name
    SET DEFAULT ENCODING ( storage_directive )
    OWNER TO new_owner / SET SCHEMA new_schema
```

**ALTER USER**

Changes the definition of a database role (user).

```
ALTER USER name RENAME TO newname
```

```
ALTER USER name SET config_parameter {TO | =} {value | DEFAULT}
```

```
ALTER USER name RESET config_parameter
```

```
ALTER USER name [ [WITH] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
    | CREATEDB | NOCREATEDB
    | CREATEROLE | NOCREATEROLE
    | CREATEUSER | NOCREATEUSER
    | INHERIT | NOINHERIT
    | LOGIN | NOLOGIN
    | [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
    | VALID UNTIL 'timestamp'
```

**ANALYZE**

Collects statistics about a database.

```
ANALYZE [VERBOSE] [table [ (column [, ...] ) ]]
```

**BEGIN**

Starts a transaction block.

```
BEGIN [WORK | TRANSACTION] [SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ
UNCOMMITTED] [READ WRITE | READ ONLY]
```

**CHECKPOINT**

Forces a transaction log checkpoint.

```
CHECKPOINT
```

**CLOSE**

Closes a cursor.

```
CLOSE cursor_name
```

**CLUSTER**

Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

```
CLUSTER indexname ON tablename
```

```
CLUSTER tablename
```

```
CLUSTER
```

**COMMENT**

Defines or change the comment of an object.

```
COMMENT ON
```

```
{ TABLE object_name |
  COLUMN table_name.column_name |
  AGGREGATE agg_name (agg_type [, ...]) |
  CAST (sourcetype AS targettype) |
  CONSTRAINT constraint_name ON table_name |
  CONVERSION object_name |
  DATABASE object_name |
  DOMAIN object_name |
  FILESPACE object_name |
  FUNCTION func_name ([[argmode] [argname] argtype [, ...]]) |
  INDEX object_name |
  LARGE OBJECT large_object_oid |
  OPERATOR op (leftoperand_type, rightoperand_type) |
  OPERATOR CLASS object_name USING index_method |
  [PROCEDURAL] LANGUAGE object_name |
  RESOURCE QUEUE object_name |
  ROLE object_name |
  RULE rule_name ON table_name |
  SCHEMA object_name |
  SEQUENCE object_name |
  TABLESPACE object_name |
  TRIGGER trigger_name ON table_name |
  TYPE object_name |
  VIEW object_name }
IS 'text'
```

**COMMIT**

Commits the current transaction.

```
COMMIT [WORK | TRANSACTION]
```

**COPY**

Copies data between a file and a table.

```
COPY table [(column [, ...])] FROM {'file' | STDIN}
[ [WITH]
  [OIDS]
  [HEADER]
  [DELIMITER [ AS ] 'delimiter']
  [NULL [ AS ] 'null string']
  [ESCAPE [ AS ] 'escape' | 'OFF']
  [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
  [CSV [QUOTE [ AS ] 'quote']
    [FORCE NOT NULL column [, ...]]
  [FILL MISSING FIELDS]
  [ [LOG ERRORS INTO error_table] [KEEP]
    SEGMENT REJECT LIMIT count [ROWS | PERCENT] ]
COPY {table [(column [, ...])] | (query)} TO {'file' | STDOUT}
[ [WITH]
  [OIDS]
  [HEADER]
  [DELIMITER [ AS ] 'delimiter']
  [NULL [ AS ] 'null string']
  [ESCAPE [ AS ] 'escape' | 'OFF']
  [CSV [QUOTE [ AS ] 'quote']
    [FORCE QUOTE column [, ...]] ]
```

**CREATE AGGREGATE**

Defines a new aggregate function.

```
CREATE [ORDERED] AGGREGATE name (input_data_type [ , ... ])
( SFUNC = sfunc,
  STYPE = state_data_type
  [, PREFUNC = pfunc]
  [, FINALFUNC = ffunc]
  [, INITCOND = initial_condition]
  [, SORTOP = sort_operator] )
```

**CREATE CAST**

Defines a new cast.

```
CREATE CAST (sourcetype AS targettype)
  WITH FUNCTION funcname (argtypes)
  [AS ASSIGNMENT | AS IMPLICIT]
CREATE CAST (sourcetype AS targettype) WITHOUT FUNCTION
  [AS ASSIGNMENT | AS IMPLICIT]
```

**CREATE CONVERSION**

Defines a new encoding conversion.

```
CREATE [DEFAULT] CONVERSION name FOR source_encoding TO dest_encoding FROM funcname
```

**CREATE DATABASE**

Creates a new database.

```
CREATE DATABASE name [ [WITH] [OWNER [=] dbowner]
                     [TEMPLATE [=] template]
                     [ENCODING [=] encoding]
                     [TABLESPACE [=] tablespace]
                     [CONNECTION LIMIT [=] connlimit ] ]
```

**CREATE DOMAIN**

Defines a new domain.

```
CREATE DOMAIN name [AS] data_type [DEFAULT expression]
    [CONSTRAINT constraint_name
    | NOT NULL | NULL
    | CHECK (expression) [...]]
```

**CREATE EXTERNAL TABLE**

Defines a new external table.

```
CREATE [READABLE] EXTERNAL TABLE table_name
    ( column_name data_type [, ...] | LIKE other_table )
    LOCATION ('file://seghost[:port]/path/file' [, ...])
    | ('gpfdist://filehost[:port]/file_pattern[#transform]'

```

## CREATE FUNCTION

Defines a new function.

```

CREATE [OR REPLACE] FUNCTION name
( [ [argmode] [argname] argtype [, ...] ] )
[ RETURNS { [ SETOF ] rettype
  | TABLE ([{ argname argtype | LIKE other table }
    [, ...]])
  } ]
{ LANGUAGE langname
| IMMUTABLE | STABLE | VOLATILE
| CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT
| [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER
| AS 'definition'
| AS 'obj_file', 'link_symbol' } ...
[ WITH ({ DESCRIBE = describe_function
  } [, ...] ) ]

```

**CREATE GROUP**

Defines a new database role.

```
CREATE GROUP name [ [WITH] option [ ... ] ]
```

where *option* can be:

```

    SUPERUSER | NOSUPERUSER
|  CREATEDB  | NOCREATEDB
|  CREATEROLE | NOCREATEROLE
|  CREATEUSER | NOCREATEUSER
|  INHERIT   | NOINHERIT
|  LOGIN     | NOLOGIN
|  [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
|  VALID UNTIL 'timestamp'
|  IN ROLE rolename [, ...]
|  IN GROUP rolename [, ...]
|  ROLE rolename [, ...]
|  ADMIN rolename [, ...]
|  USER rolename [, ...]
|  SYSID uid
```

**CREATE INDEX**

Defines a new index.

```

CREATE [UNIQUE] INDEX name ON table
    [USING btree|bitmap|gist]
    ( {column | (expression)} [opclass] [, ...] )
    [ WITH ( FILLFACTOR = value ) ]
    [TABLESPACE tablespace]
    [WHERE predicate]
```

**CREATE LANGUAGE**

Defines a new procedural language.

```

CREATE [PROCEDURAL] LANGUAGE name
CREATE [TRUSTED] [PROCEDURAL] LANGUAGE name
    HANDLER call_handler [VALIDATOR valfunction]
```

**CREATE OPERATOR**

Defines a new operator.

```

CREATE OPERATOR name (
    PROCEDURE = funcname
    [, LEFTARG = lefttype] [, RIGHTARG = righttype]
    [, COMMUTATOR = com_op] [, NEGATOR = neg_op]
    [, RESTRICT = res_proc] [, JOIN = join_proc]
    [, HASHES] [, MERGES]
    [, SORT1 = left_sort_op] [, SORT2 = right_sort_op]
    [, LTCMP = less_than_op] [, GTCMP = greater_than_op] )
```

**CREATE OPERATOR CLASS**

Defines a new operator class.

```
CREATE OPERATOR CLASS name [DEFAULT] FOR TYPE data_type
  USING index_method AS
  {
    OPERATOR strategy_number op_name [(op_type, op_type)] [RECHECK]
    | FUNCTION support_number funcname (argument_type [, ...] )
    | STORAGE storage_type
  } [, ... ]
```

**CREATE RESOURCE QUEUE**

Defines a new resource queue.

```
CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])
```

where *queue\_attribute* is:

```
  ACTIVE_STATEMENTS=integer
    [ MAX_COST=float [COST_OVERCOMMIT={TRUE|FALSE}] ]
    [ MIN_COST=float ]
    [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
    [ MEMORY_LIMIT='memory_units' ]
| MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
  [ ACTIVE_STATEMENTS=integer ]
  [ MIN_COST=float ]
  [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
  [ MEMORY_LIMIT='memory_units' ]
```

**CREATE ROLE**

Defines a new database role (user or group).

```
CREATE ROLE name [[WITH] option [ ... ]]
```

where *option* can be:

```
  SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEEXTTABLE | NOCREATEEXTTABLE
| ( ( attribute='value' [, ...] ) )
    where attributes and values are:
      type='readable'|'writable'
      protocol='gpfdist' | 'http'
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| CONNECTION LIMIT conlimit
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'
| IN ROLE rolename [, ...]
| ROLE rolename [, ...]
| ADMIN rolename [, ...]
| RESOURCE QUEUE queue_name
| [ DENY deny_point ]
| [ DENY BETWEEN deny_point AND deny_point]
```

**CREATE RULE**

Defines a new rewrite rule.

```
CREATE [OR REPLACE] RULE name AS ON event
  TO table [WHERE condition]
  DO [ALSO | INSTEAD] { NOTHING | command | (command; command ...) }
```

**CREATE SCHEMA**

Defines a new schema.

```
CREATE SCHEMA schema_name [AUTHORIZATION username] [schema_element [ ... ]]
CREATE SCHEMA AUTHORIZATION rolename [schema_element [ ... ]]
```

**CREATE SEQUENCE**

Defines a new sequence generator.

```
CREATE [TEMPORARY | TEMP] SEQUENCE name
  [INCREMENT [BY] value]
  [MINVALUE minvalue | NO MINVALUE]
  [MAXVALUE maxvalue | NO MAXVALUE]
  [START [ WITH ] start]
  [CACHE cache]
  [[NO] CYCLE]
  [OWNED BY { table.column | NONE }]
```

**CREATE TABLE**

Defines a new table.

```
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name (
[ { column_name data_type [ DEFAULT default_expr ]      [column_constraint [ ... ] ]
[ ENCODING ( storage_directive [,...] ) ]
]

**CREATE TABLE AS**

Defines a new table from the results of a query.

```
CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} ] TABLE table_name
    [(column_name [, ...] )]
    [ WITH ( storage_parameter=value [, ...] ) ]
    [ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP}]
    [TABLESPACE tablespace]
    AS query
    [DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY]
```

where *storage\_parameter* is:

```
APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
COMPRESSTYPE={ZLIB|QUICKLZ}
COMPRESSLEVEL={1-9 | 1}
FILLFACTOR={10-100}
OIDS [=TRUE|FALSE]
```

**CREATE TABLESPACE**

Defines a new tablespace.

```
CREATE TABLESPACE tablespace_name [OWNER username]
    FILESPACE filespace_name
```

**CREATE TRIGGER**

Defines a new trigger. User-defined triggers are not supported in Greenplum Database.

```
CREATE TRIGGER name {BEFORE | AFTER} {event [OR ...]}
    ON table [ FOR [EACH] {ROW | STATEMENT} ]
    EXECUTE PROCEDURE funcname ( arguments )
```

**CREATE TYPE**

Defines a new data type.

```
CREATE TYPE name AS ( attribute_name data_type [, ...] )
CREATE TYPE name (
    INPUT = input_function,
    OUTPUT = output_function
    [, RECEIVE = receive_function]
    [, SEND = send_function]
    [, INTERNALLENGTH = {internallength | VARIABLE}]
    [, PASSEDBYVALUE]
    [, ALIGNMENT = alignment]
    [, STORAGE = storage]
    [, DEFAULT = default]
    [, ELEMENT = element]
    [, DELIMITER = delimiter]
    [, COMPRESSTYPE = compression_type]
    [, COMPRESSLEVEL = compression_level]
    [, BLOCKSIZE= blocksize]
)
CREATE TYPE name
```

**CREATE USER**

Defines a new database role with the LOGIN privilege by default.

```
CREATE USER name [ [WITH] option [ ... ] ]
```

where *option* can be:

```

    SUPERUSER | NOSUPERUSER
  | CREATEDB | NOCREATEDB
  | CREATEROLE | NOCREATEROLE
  | CREATEUSER | NOCREATEUSER
  | INHERIT | NOINHERIT
  | LOGIN | NOLOGIN
  | [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
  | VALID UNTIL 'timestamp'
  | IN ROLE rolename [, ...]
  | IN GROUP rolename [, ...]
  | ROLE rolename [, ...]
  | ADMIN rolename [, ...]
  | USER rolename [, ...]
  | SYSID uid
  | RESOURCE QUEUE queue_name
```

**CREATE VIEW**

Defines a new view.

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] VIEW name
    [ ( column_name [, ...] ) ]
    AS query
```

**DEALLOCATE**

Deallocates a prepared statement.

```
DEALLOCATE [PREPARE] name
```

**DECLARE**

Defines a cursor.

```
DECLARE name [BINARY] [INSENSITIVE] [NO SCROLL] CURSOR
    [{WITH | WITHOUT} HOLD]
    FOR query [FOR READ ONLY]
```

**DELETE**

Deletes rows from a table.

```
DELETE FROM [ONLY] table [[AS] alias]
    [USING usinglist]
    [WHERE condition]
```

**DROP AGGREGATE**

Removes an aggregate function.

```
DROP AGGREGATE [IF EXISTS] name ( type [, ...] ) [CASCADE | RESTRICT]
```

**DROP CAST**

Removes a cast.

```
DROP CAST [IF EXISTS] (sourcetype AS targettype) [CASCADE | RESTRICT]
```

**DROP CONVERSION**

Removes a conversion.

```
DROP CONVERSION [IF EXISTS] name [CASCADE | RESTRICT]
```

**DROP DATABASE**

Removes a database.

```
DROP DATABASE [IF EXISTS] name
```

**DROP DOMAIN**

Removes a domain.

```
DROP DOMAIN [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**DROP EXTERNAL TABLE**

Removes an external table definition.

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] name [CASCADE | RESTRICT]
```

**DROP FILESPACE**

Removes a filesystem.

```
DROP FILESPACE [IF EXISTS] filesystemname
```

**DROP FUNCTION**

Removes a function.

```
DROP FUNCTION [IF EXISTS] name ( [ argmode ] argname argtype [, ...] ) [CASCADE  
| RESTRICT]
```

**DROP GROUP**

Removes a database role.

```
DROP GROUP [IF EXISTS] name [, ...]
```

**DROP INDEX**

Removes an index.

```
DROP INDEX [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**DROP LANGUAGE**

Removes a procedural language.

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] name [CASCADE | RESTRICT]
```

**DROP OPERATOR**

Removes an operator.

```
DROP OPERATOR [IF EXISTS] name ( {lefttype | NONE} , {righttype | NONE} ) [CASCADE  
| RESTRICT]
```

**DROP OPERATOR CLASS**

Removes an operator class.

```
DROP OPERATOR CLASS [IF EXISTS] name USING index_method [CASCADE | RESTRICT]
```

**DROP OWNED**

Removes database objects owned by a database role.

```
DROP OWNED BY name [, ...] [CASCADE | RESTRICT]
```

**DROP RESOURCE QUEUE**

Removes a resource queue.

```
DROP RESOURCE QUEUE queue_name
```

**DROP ROLE**

Removes a database role.

```
DROP ROLE [IF EXISTS] name [, ...]
```

**DROP RULE**

Removes a rewrite rule.

```
DROP RULE [IF EXISTS] name ON relation [CASCADE | RESTRICT]
```

**DROP SCHEMA**

Removes a schema.

```
DROP SCHEMA [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**DROP SEQUENCE**

Removes a sequence.

```
DROP SEQUENCE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**DROP TABLE**

Removes a table.

```
DROP TABLE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**DROP TABLESPACE**

Removes a tablespace.

```
DROP TABLESPACE [IF EXISTS] tablespacename
```

**DROP TRIGGER**

Removes a trigger.

```
DROP TRIGGER [IF EXISTS] name ON table [CASCADE | RESTRICT]
```

**DROP TYPE**

Removes a data type.

```
DROP TYPE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**DROP USER**

Removes a database role.

```
DROP USER [IF EXISTS] name [, ...]
```

**DROP VIEW**

Removes a view.

```
DROP VIEW [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

**END**

Commits the current transaction.

```
END [WORK | TRANSACTION]
```

**EXECUTE**

Executes a prepared SQL statement.

```
EXECUTE name [ (parameter [, ...] ) ]
```

**EXPLAIN**

Shows the query plan of a statement.

```
EXPLAIN [ANALYZE] [VERBOSE] statement
```

**FETCH**

Retrieves rows from a query using a cursor.

```
FETCH [ forward_direction { FROM | IN } ] cursorname
```

*where forward\_direction can be empty or one of:*

```
NEXT
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
```

**GRANT**

Defines access privileges.

```
GRANT { {SELECT | INSERT | UPDATE | DELETE | REFERENCES | TRIGGER} [, ...] | ALL [PRIV-
```

```

ILEGES] }
    ON [TABLE] tablename [, ...]
    TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]
GRANT { {USAGE | SELECT | UPDATE} [,...] | ALL [PRIVILEGES] }
    ON SEQUENCE sequencename [, ...]
    TO { rolename | PUBLIC } [, ...] [WITH GRANT OPTION]
GRANT { {CREATE | CONNECT | TEMPORARY | TEMP} [,...] | ALL [PRIVILEGES] }
    ON DATABASE dbname [, ...]
    TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]
GRANT { EXECUTE | ALL [PRIVILEGES] }
    ON FUNCTION funcname ( [ [argmode] [argname] argtype [, ...] ] ) [, ...]
    TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]
GRANT { USAGE | ALL [PRIVILEGES] }
    ON LANGUAGE langname [, ...]
    TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]
GRANT { {CREATE | USAGE} [,...] | ALL [PRIVILEGES] }
    ON SCHEMA schemaname [, ...]
    TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]

    ON TABLESPACE tablespacename [, ...]
    TO {rolename | PUBLIC} [, ...] [WITH GRANT OPTION]
GRANT parent_role [, ...]
    TO member_role [, ...] [WITH ADMIN OPTION]
GRANT { SELECT | INSERT | ALL [PRIVILEGES] }
    ON PROTOCOL protocolname
    TO username

```

## INSERT

Creates new rows in a table.

```

INSERT INTO table [( column [, ...] )]
    {DEFAULT VALUES | VALUES ( {expression | DEFAULT} [, ...] ) [, ...] | query}

```

## LOAD

Loads or reloads a shared library file.

```

LOAD 'filename'

```

## LOCK

Locks a table.

```

LOCK [TABLE] name [, ...] [IN lockmode MODE] [NOWAIT]

```

where *lockmode* is one of:

```

ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE | SHARE | SHARE ROW
EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE

```

**MOVE**

Positions a cursor.

```
MOVE [ forward_direction {FROM | IN} ] cursorname
```

where *direction* can be empty or one of:

```
NEXT
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
```

**PREPARE**

Prepare a statement for execution.

```
PREPARE name [ (datatype [, ...] ) ] AS statement
```

**REASSIGN OWNED**

Changes the ownership of database objects owned by a database role.

```
REASSIGN OWNED BY old_role [, ...] TO new_role
```

**REINDEX**

Rebuilds indexes.

```
REINDEX {INDEX | TABLE | DATABASE | SYSTEM} name
```

**RELEASE SAVEPOINT**

Destroys a previously defined savepoint.

```
RELEASE [SAVEPOINT] savepoint_name
```

**RESET**

Restores the value of a system configuration parameter to the default value.

```
RESET configuration_parameter
```

```
RESET ALL
```

**REVOKE**

Removes access privileges.

```

REVOKE [GRANT OPTION FOR] { {SELECT | INSERT | UPDATE | DELETE
    | REFERENCES | TRIGGER} [,...] | ALL [PRIVILEGES] }
    ON [TABLE] tablename [, ...]
    FROM {rolename | PUBLIC} [, ...]
    [CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { {USAGE | SELECT | UPDATE} [,...]
    | ALL [PRIVILEGES] }
    ON SEQUENCE sequencename [, ...]
    FROM { rolename | PUBLIC } [, ...]
    [CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { {CREATE | CONNECT
    | TEMPORARY | TEMP} [,...] | ALL [PRIVILEGES] }
    ON DATABASE dbname [, ...]
    FROM {rolename | PUBLIC} [, ...]
    [CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] {EXECUTE | ALL [PRIVILEGES]}
    ON FUNCTION funcname ( [[argmode] [argname] argtype
        [, ...]] ) [, ...]
    FROM {rolename | PUBLIC} [, ...]
    [CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] {USAGE | ALL [PRIVILEGES]}
    ON LANGUAGE langname [, ...]
    FROM {rolename | PUBLIC} [, ...]
    [ CASCADE | RESTRICT ]

REVOKE [GRANT OPTION FOR] { {CREATE | USAGE} [,...]
    | ALL [PRIVILEGES] }
    ON SCHEMA schemaname [, ...]
    FROM {rolename | PUBLIC} [, ...]
    [CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { CREATE | ALL [PRIVILEGES] }
    ON TABLESPACE tablespacename [, ...]
    FROM { rolename | PUBLIC } [, ...]
    [CASCADE | RESTRICT]

REVOKE [ADMIN OPTION FOR] parent_role [, ...]
    FROM member_role [, ...]
    [CASCADE | RESTRICT]

```

**ROLLBACK**

Aborts the current transaction.

```
ROLLBACK [WORK | TRANSACTION]
```

**ROLLBACK TO SAVEPOINT**

Rolls back the current transaction to a savepoint.

```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name
```

**SAVEPOINT**

Defines a new savepoint within the current transaction.

```
SAVEPOINT savepoint_name
```

**SELECT**

Retrieves rows from a table or view.

```
SELECT [ALL | DISTINCT [ON (expression [, ...])]]
  * | expression [[AS] output_name] [, ...]
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY grouping_element [, ...]]
[HAVING condition [, ...]]
[WINDOW window_name AS (window_specification)]
[{UNION | INTERSECT | EXCEPT} [ALL] select]
[ORDER BY expression [ASC | DESC | USING operator] [, ...]]
[LIMIT {count | ALL}]
[OFFSET start]
[FOR {UPDATE | SHARE} [OF table_name [, ...]] [NOWAIT] [...]]
```

where *grouping\_element* can be one of:

```
()
expression
ROLLUP (expression [...])
CUBE (expression [...])
GROUPING SETS ((grouping_element [, ...]))
```

where *window\_specification* can be:

```
[window_name]
[PARTITION BY expression [, ...]]
[ORDER BY expression [ASC | DESC | USING operator] [, ...]]
  [{RANGE | ROWS}
    { UNBOUNDED PRECEDING
      | expression PRECEDING
      | CURRENT ROW
      | BETWEEN window_frame_bound AND window_frame_bound }]]
```

where *window\_frame\_bound* can be one of:

```
UNBOUNDED PRECEDING
expression PRECEDING
CURRENT ROW
expression FOLLOWING
UNBOUNDED FOLLOWING
```

where *from\_item* can be one of:

```
[ONLY] table_name [[AS] alias [( column_alias [, ...] )]]
(select) [AS] alias [( column_alias [, ...] )]
function_name ( [argument [, ...]] ) [AS] alias
  [( column_alias [, ...]
    | column_definition [, ...] )]
function_name ( [argument [, ...]] ) AS
  ( column_definition [, ...] )
from_item [NATURAL] join_type from_item
  [ON join_condition | USING ( join_column [, ...] )]
```

**SELECT INTO**

Defines a new table from the results of a query.

```
SELECT [ALL | DISTINCT [ON ( expression [, ...] )]]
      * | expression [AS output_name] [, ...]
INTO [TEMPORARY | TEMP] [TABLE] new_table
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY expression [, ...]]
[HAVING condition [, ...]]
[{{UNION | INTERSECT | EXCEPT} [ALL] select}
[ORDER BY expression [ASC | DESC | USING operator] [, ...]]
[LIMIT {count | ALL}]
[OFFSET start]
[FOR {UPDATE | SHARE} [OF table_name [, ...]] [NOWAIT] [...]]
```

**SET**

Changes the value of a Greenplum Database configuration parameter.

```
SET [SESSION | LOCAL] configuration_parameter {TO | =} value | 'value' | DEFAULT}
SET [SESSION | LOCAL] TIME ZONE {timezone | LOCAL | DEFAULT}
```

**SET ROLE**

Sets the current role identifier of the current session.

```
SET [SESSION | LOCAL] ROLE rolename
SET [SESSION | LOCAL] ROLE NONE
RESET ROLE
```

**SET SESSION AUTHORIZATION**

Sets the session role identifier and the current role identifier of the current session.

```
SET [SESSION | LOCAL] SESSION AUTHORIZATION rolename
SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

**SET TRANSACTION**

Sets the characteristics of the current transaction.

```
SET TRANSACTION transaction_mode [, ...]
SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode [, ...]
where transaction_mode is one of:
ISOLATION LEVEL {SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED}
READ WRITE | READ ONLY
```

**SHOW**

Shows the value of a system configuration parameter.

```
SHOW configuration_parameter
SHOW ALL
```

**START TRANSACTION**

Starts a transaction block.

```
START TRANSACTION [SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED]
[READ WRITE | READ ONLY]
```

**TRUNCATE**

Empties a table of all rows.

```
TRUNCATE [TABLE] name [, ...] [CASCADE | RESTRICT]
```

**UPDATE**

Updates rows of a table.

```
UPDATE [ONLY] table [[AS] alias]
  SET {column = {expression | DEFAULT} |
      (column [, ...]) = ({expression | DEFAULT} [, ...])} [, ...]
  [FROM fromlist]
  [WHERE condition]
```

**VACUUM**

Garbage-collects and optionally analyzes a database.

```
VACUUM [FULL] [FREEZE] [VERBOSE] [table]
VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE
      [table [(column [, ...] )]]
```

**VALUES**

Computes a set of rows.

```
VALUES ( expression [, ...] ) [, ...]
[ORDER BY sort_expression [ASC | DESC | USING operator] [, ...]]
[LIMIT {count | ALL}] [OFFSET start]
```

---

## ABORT

Aborts the current transaction.

---

### Synopsis

ABORT [WORK | TRANSACTION]

---

### Description

ABORT rolls back the current transaction and causes all the updates made by the transaction to be discarded. This command is identical in behavior to the standard SQL command [ROLLBACK](#), and is present only for historical reasons.

---

### Parameters

**WORK**  
**TRANSACTION**

Optional key words. They have no effect.

---

### Notes

Use COMMIT to successfully terminate a transaction.

Issuing ABORT when not inside a transaction does no harm, but it will provoke a warning message.

---

### Compatibility

This command is a Greenplum Database extension present for historical reasons. ROLLBACK is the equivalent standard SQL command.

---

### See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK](#)

---

## ALTER AGGREGATE

Changes the definition of an aggregate function

---

### Synopsis

```
ALTER AGGREGATE name ( type [ , ... ] ) RENAME TO new_name
ALTER AGGREGATE name ( type [ , ... ] ) OWNER TO new_owner
ALTER AGGREGATE name ( type [ , ... ] ) SET SCHEMA new_schema
```

---

### Description

ALTER AGGREGATE changes the definition of an aggregate function.

You must own the aggregate function to use ALTER AGGREGATE. To change the schema of an aggregate function, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the aggregate function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the aggregate function. However, a superuser can alter ownership of any aggregate function anyway.)

---

### Parameters

#### *name*

The name (optionally schema-qualified) of an existing aggregate function.

#### *type*

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write \* in place of the list of input data types.

#### *new\_name*

The new name of the aggregate function.

#### *new\_owner*

The new owner of the aggregate function.

#### *new\_schema*

The new schema for the aggregate function.

---

### Examples

To rename the aggregate function *myavg* for type *integer* to *my\_average*:

```
ALTER AGGREGATE myavg(integer) RENAME TO my_average;
```

To change the owner of the aggregate function *myavg* for type *integer* to *joe*:

```
ALTER AGGREGATE myavg(integer) OWNER TO joe;
```

To move the aggregate function *myavg* for type *integer* into schema *myschema*:

```
ALTER AGGREGATE myavg(integer) SET SCHEMA myschema;
```

---

### Compatibility

There is no `ALTER AGGREGATE` statement in the SQL standard.

---

### See Also

[CREATE AGGREGATE](#), [DROP AGGREGATE](#)

---

## ALTER CONVERSION

Changes the definition of a conversion.

---

### Synopsis

```
ALTER CONVERSION name RENAME TO newname
```

```
ALTER CONVERSION name OWNER TO newowner
```

---

### Description

ALTER CONVERSION changes the definition of a conversion.

You must own the conversion to use ALTER CONVERSION. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the conversion's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the conversion. However, a superuser can alter ownership of any conversion anyway.)

---

### Parameters

***name***

The name (optionally schema-qualified) of an existing conversion.

***newname***

The new name of the conversion.

***newowner***

The new owner of the conversion.

---

### Examples

To rename the conversion *iso\_8859\_1\_to\_utf8* to *latin1\_to\_unicode*:

```
ALTER CONVERSION iso_8859_1_to_utf8 RENAME TO  
latin1_to_unicode;
```

To change the owner of the conversion *iso\_8859\_1\_to\_utf8* to *joe*:

```
ALTER CONVERSION iso_8859_1_to_utf8 OWNER TO joe;
```

---

### Compatibility

There is no ALTER CONVERSION statement in the SQL standard.

---

### See Also

[CREATE CONVERSION](#), [DROP CONVERSION](#)

---

## ALTER DATABASE

Changes the attributes of a database.

---

### Synopsis

```
ALTER DATABASE name [ WITH CONNECTION LIMIT conlimit ]
ALTER DATABASE name SET parameter { TO | = } { value | DEFAULT }
ALTER DATABASE name RESET parameter
ALTER DATABASE name RENAME TO newname
ALTER DATABASE name OWNER TO new_owner
```

---

### Description

ALTER DATABASE changes the attributes of a database.

The first form changes the allowed connection limit for a database. Only the database owner or a superuser can change this setting.

The second and third forms change the session default for a configuration parameter for a Greenplum database. Whenever a new session is subsequently started in that database, the specified value becomes the session default value. The database-specific default overrides whatever setting is present in the server configuration file (`postgresql.conf`). Only the database owner or a superuser can change the session defaults for a database. Certain parameters cannot be set this way, or can only be set by a superuser.

The fourth form changes the name of the database. Only the database owner or a superuser can rename a database; non-superuser owners must also have the `CREATEDB` privilege. You cannot rename the current database. Connect to a different database first.

The fifth form changes the owner of the database. To alter the owner, you must own the database and also be a direct or indirect member of the new owning role, and you must have the `CREATEDB` privilege. (Note that superusers have all these privileges automatically.)

---

### Parameters

#### *name*

The name of the database whose attributes are to be altered.

#### *conlimit*

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

***parameter  
value***

Set this database's session default for the specified configuration parameter to the given value. If value is `DEFAULT` or, equivalently, `RESET` is used, the database-specific setting is removed, so the system-wide default setting will be inherited in new sessions. Use `RESET ALL` to clear all database-specific settings. See [“Server Configuration Parameters”](#) on page 476 for information about server parameters. for information about all user-settable configuration parameters.

***newname***

The new name of the database.

***new\_owner***

The new owner of the database.

---

## Notes

It is also possible to set a configuration parameter session default for a specific role (user) rather than to a database. Role-specific settings override database-specific ones if there is a conflict. See `ALTER ROLE`.

---

## Examples

To set the default schema search path for the *mydatabase* database:

```
ALTER DATABASE mydatabase SET search_path TO myschema,
public, pg_catalog;
```

---

## Compatibility

The `ALTER DATABASE` statement is a Greenplum Database extension.

---

## See Also

[CREATE DATABASE](#), [DROP DATABASE](#), [SET](#)

---

## ALTER DOMAIN

Changes the definition of a domain.

---

### Synopsis

```
ALTER DOMAIN name { SET DEFAULT expression | DROP DEFAULT }
ALTER DOMAIN name { SET | DROP } NOT NULL
ALTER DOMAIN name ADD domain_constraint
ALTER DOMAIN name DROP CONSTRAINT constraint_name [RESTRICT |
CASCADE]
ALTER DOMAIN name OWNER TO new_owner
ALTER DOMAIN name SET SCHEMA new_schema
```

---

### Description

ALTER DOMAIN changes the definition of an existing domain. There are several sub-forms:

- **SET/DROP DEFAULT** — These forms set or remove the default value for a domain. Note that defaults only apply to subsequent INSERT commands. They do not affect rows already in a table using the domain.
- **SET/DROP NOT NULL** — These forms change whether a domain is marked to allow NULL values or to reject NULL values. You may only SET NOT NULL when the columns using the domain contain no null values.
- **ADD domain\_constraint** — This form adds a new constraint to a domain using the same syntax as CREATE DOMAIN. This will only succeed if all columns using the domain satisfy the new constraint.
- **DROP CONSTRAINT** — This form drops constraints on a domain.
- **OWNER** — This form changes the owner of the domain to the specified user.
- **SET SCHEMA** — This form changes the schema of the domain. Any constraints associated with the domain are moved into the new schema as well.

You must own the domain to use ALTER DOMAIN. To change the schema of a domain, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the domain's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the domain. However, a superuser can alter ownership of any domain anyway.)

---

### Parameters

***name***

The name (optionally schema-qualified) of an existing domain to alter.

***domain\_constraint***

New domain constraint for the domain.

***constraint\_name***

Name of an existing constraint to drop.

**CASCADE**

Automatically drop objects that depend on the constraint.

**RESTRICT**

Refuse to drop the constraint if there are any dependent objects. This is the default behavior.

***new\_owner***

The user name of the new owner of the domain.

***new\_schema***

The new schema for the domain.

---

**Examples**

To add a NOT NULL constraint to a domain:

```
ALTER DOMAIN zipcode SET NOT NULL;
```

To remove a NOT NULL constraint from a domain:

```
ALTER DOMAIN zipcode DROP NOT NULL;
```

To add a check constraint to a domain:

```
ALTER DOMAIN zipcode ADD CONSTRAINT zipchk CHECK
(char_length(VALUE) = 5);
```

To remove a check constraint from a domain:

```
ALTER DOMAIN zipcode DROP CONSTRAINT zipchk;
```

To move the domain into a different schema:

```
ALTER DOMAIN zipcode SET SCHEMA customers;
```

---

**Compatibility**

ALTER DOMAIN conforms to the SQL standard, except for the OWNER and SET SCHEMA variants, which are Greenplum Database extensions.

---

**See Also**

[CREATE DOMAIN](#), [DROP DOMAIN](#)

---

## ALTER EXTERNAL TABLE

Changes the definition of an external table.

---

### Synopsis

```
ALTER EXTERNAL TABLE name RENAME [COLUMN] column TO new_column
```

```
ALTER EXTERNAL TABLE name RENAME TO new_name
```

```
ALTER EXTERNAL TABLE name SET SCHEMA new_schema
```

```
ALTER EXTERNAL TABLE name action [, ... ]
```

where *action* is one of:

```
ADD [COLUMN] column_name type
```

```
DROP [COLUMN] column
```

```
ALTER [COLUMN] column TYPE type [USING expression]
```

```
OWNER TO new_owner
```

---

### Description

ALTER EXTERNAL TABLE changes the definition of an existing external table. There are several subforms:

- **ADD COLUMN** — Adds a new column to the external table definition.
- **DROP COLUMN** — Drops a column from the external table definition. Note that if you drop readable external table columns, it only changes the table definition in Greenplum Database. External data files are not changed.
- **ALTER COLUMN TYPE** — Changes the data type of a column of a table. The optional USING clause specifies how to compute the new column value from the old. If omitted, the default conversion is the same as an assignment cast from old data type to new. A USING clause must be provided if there is no implicit or assignment cast from the old to new type.
- **OWNER** — Changes the owner of the external table to the specified user.
- **RENAME** — Changes the name of an external table or the name of an individual column in the table. There is no effect on the external data.
- **SET SCHEMA** — Moves the external table into another schema.

You must own the external table to use ALTER EXTERNAL TABLE. To change the schema of an external table, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the external table's schema. A superuser has these privileges automatically.

In this release, ALTER EXTERNAL TABLE cannot modify the external table type, the data format, or the location of the external data. To modify this information, you must drop and recreate the external table definition.

---

## Parameters

***name***

The name (possibly schema-qualified) of an existing external table definition to alter.

***column***

Name of a new or existing column.

***new\_column***

New name for an existing column.

***new\_name***

New name for the external table.

***type***

Data type of the new column, or new data type for an existing column.

***new\_owner***

The role name of the new owner of the external table.

***new\_schema***

The name of the schema to which the external table will be moved.

---

## Examples

Add a new column to an external table definition:

```
ALTER EXTERNAL TABLE ext_expenses ADD COLUMN manager text;
```

Change the name of an external table:

```
ALTER EXTERNAL TABLE ext_data RENAME TO ext_sales_data;
```

Change the owner of an external table:

```
ALTER EXTERNAL TABLE ext_data OWNER TO jojo;
```

Change the schema of an external table:

```
ALTER EXTERNAL TABLE ext_leads SET SCHEMA marketing;
```

---

## Compatibility

`ALTER EXTERNAL TABLE` is a Greenplum Database extension. There is no `ALTER EXTERNAL TABLE` statement in the SQL standard or regular PostgreSQL.

---

## See Also

[CREATE EXTERNAL TABLE](#), [DROP EXTERNAL TABLE](#)

---

## ALTER FILESPACE

Changes the definition of a filesystem.

---

### Synopsis

```
ALTER FILESPACE name RENAME TO newname
```

```
ALTER FILESPACE name OWNER TO newowner
```

---

### Description

ALTER FILESPACE changes the definition of a filesystem.

You must own the filesystem to use ALTER FILESPACE. To alter the owner, you must also be a direct or indirect member of the new owning role (note that superusers have these privileges automatically).

---

### Parameters

***name***

The name of an existing filesystem.

***newname***

The new name of the filesystem. The new name cannot begin with *pg\_* or *gp\_* (reserved for system filesystems).

***newowner***

The new owner of the filesystem.

---

### Examples

Rename filesystem *myfs* to *fast\_ssd*:

```
ALTER FILESPACE myfs RENAME TO fast_ssd;
```

Change the owner of tablespace *mysf*:

```
ALTER FILESPACE myfs OWNER TO dba;
```

---

### Compatibility

There is no ALTER FILESPACE statement in the SQL standard or in PostgreSQL.

---

### See Also

[DROP FILESPACE](#), `gpfilesystem` in the *Greenplum Database Utility Guide*

---

## ALTER FUNCTION

Changes the definition of a function.

---

### Synopsis

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
action [, ... ] [RESTRICT]
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
RENAME TO new_name
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
OWNER TO new_owner
```

```
ALTER FUNCTION name ( [ [argmode] [argname] argtype [, ...] ] )
SET SCHEMA new_schema
```

where *action* is one of:

```
{ CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
{ IMMUTABLE | STABLE | VOLATILE }
{ [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
```

---

### Description

ALTER FUNCTION changes the definition of a function.

You must own the function to use ALTER FUNCTION. To change a function's schema, you must also have CREATE privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the function. However, a superuser can alter ownership of any function anyway.)

---

### Parameters

#### *name*

The name (optionally schema-qualified) of an existing function.

#### *argmode*

The mode of an argument: either IN, OUT, or INOUT. If omitted, the default is IN.

Note that ALTER FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN and INOUT arguments.

#### *argname*

The name of an argument. Note that ALTER FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

***argtype***

The data type(s) of the function's arguments (optionally schema-qualified), if any.

***new\_name***

The new name of the function.

***new\_owner***

The new owner of the function. Note that if the function is marked `SECURITY DEFINER`, it will subsequently execute as the new owner.

***new\_schema***

The new schema for the function.

**CALLED ON NULL INPUT**  
**RETURNS NULL ON NULL INPUT**  
**STRICT**

`CALLED ON NULL INPUT` changes the function so that it will be invoked when some or all of its arguments are null. `RETURNS NULL ON NULL INPUT` or `STRICT` changes the function so that it is not invoked if any of its arguments are null; instead, a null result is assumed automatically. See `CREATE FUNCTION` for more information.

**IMMUTABLE**  
**STABLE**  
**VOLATILE**

Change the volatility of the function to the specified setting. See `CREATE FUNCTION` for details.

**[ EXTERNAL ] SECURITY INVOKER**  
**[ EXTERNAL ] SECURITY DEFINER**

Change whether the function is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See `CREATE FUNCTION` for more information about this capability.

**RESTRICT**

Ignored for conformance with the SQL standard.

---

**Notes**

Greenplum Database has limitations on the use of functions defined as `STABLE` or `VOLATILE`. See [CREATE FUNCTION](#) for more information.

---

**Examples**

To rename the function `sqrt` for type `integer` to `square_root`:

```
ALTER FUNCTION sqrt(integer) RENAME TO square_root;
```

To change the owner of the function `sqrt` for type `integer` to `joe`:

```
ALTER FUNCTION sqrt(integer) OWNER TO joe;
```

To change the *schema* of the function *sqrt* for type *integer* to *math*:

```
ALTER FUNCTION sqrt(integer) SET SCHEMA math;
```

---

### Compatibility

This statement is partially compatible with the `ALTER FUNCTION` statement in the SQL standard. The standard allows more properties of a function to be modified, but does not provide the ability to rename a function, make a function a security definer, or change the owner, schema, or volatility of a function. The standard also requires the `RESTRICT` key word, which is optional in Greenplum Database.

---

### See Also

[CREATE FUNCTION](#), [DROP FUNCTION](#)

---

## ALTER GROUP

Changes a role name or membership.

---

### Synopsis

```
ALTER GROUP groupname ADD USER username [, ... ]
```

```
ALTER GROUP groupname DROP USER username [, ... ]
```

```
ALTER GROUP groupname RENAME TO newname
```

---

### Description

`ALTER GROUP` is an obsolete command, though still accepted for backwards compatibility. Groups (and users) have been superseded by the more general concept of roles. See [ALTER ROLE](#) for more information.

---

### Parameters

#### *groupname*

The name of the group (role) to modify.

#### *username*

Users (roles) that are to be added to or removed from the group. The users (roles) must already exist.

#### *newname*

The new name of the group (role).

---

### Examples

To add users to a group:

```
ALTER GROUP staff ADD USER karl, john;
```

To remove a user from a group:

```
ALTER GROUP workers DROP USER beth;
```

---

### Compatibility

There is no `ALTER GROUP` statement in the SQL standard.

---

### See Also

[ALTER ROLE](#), [GRANT](#), [REVOKE](#)

---

## ALTER INDEX

Changes the definition of an index.

---

### Synopsis

```
ALTER INDEX name RENAME TO new_name
ALTER INDEX name SET TABLESPACE tablespace_name
ALTER INDEX name SET ( FILLFACTOR = value )
ALTER INDEX name RESET ( FILLFACTOR )
```

---

### Description

ALTER INDEX changes the definition of an existing index. There are several subforms:

- **RENAME** — Changes the name of the index. There is no effect on the stored data.
- **SET TABLESPACE** — Changes the index's tablespace to the specified tablespace and moves the data file(s) associated with the index to the new tablespace. See also CREATE TABLESPACE.
- **SET FILLFACTOR** — Changes the index-method-specific storage parameters for the index. The built-in index methods all accept a single parameter: FILLFACTOR. The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. Index contents will not be modified immediately by this command. Use REINDEX to rebuild the index to get the desired effects.
- **RESET FILLFACTOR** — Resets FILLFACTOR to the default. As with SET, a REINDEX may be needed to update the index entirely.

---

### Parameters

#### *name*

The name (optionally schema-qualified) of an existing index to alter.

#### *new\_name*

New name for the index.

#### *tablespace\_name*

The tablespace to which the index will be moved.

#### **FILLFACTOR**

The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index's efficiency.

B-trees use a default fillfactor of 90, but any value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index's physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

---

## Notes

These operations are also possible using `ALTER TABLE`.

Changing any part of a system catalog index is not permitted.

---

## Examples

To rename an existing index:

```
ALTER INDEX distributors RENAME TO suppliers;
```

To move an index to a different tablespace:

```
ALTER INDEX distributors SET TABLESPACE fasttablespace;
```

To change an index's fill factor (assuming that the index method supports it):

```
ALTER INDEX distributors SET (fillfactor = 75);  
REINDEX INDEX distributors;
```

---

## Compatibility

`ALTER INDEX` is a Greenplum Database extension.

---

## See Also

[CREATE INDEX](#), [REINDEX](#), [ALTER TABLE](#)

---

## ALTER LANGUAGE

Changes the name of a procedural language.

---

### Synopsis

```
ALTER LANGUAGE name RENAME TO newname
```

---

### Description

ALTER LANGUAGE changes the name of a procedural language. Only a superuser can rename languages.

---

### Parameters

*name*

Name of a language.

*newname*

The new name of the language.

---

### Compatibility

There is no ALTER LANGUAGE statement in the SQL standard.

---

### See Also

[CREATE LANGUAGE](#), [DROP LANGUAGE](#)

---

## ALTER OPERATOR

Changes the definition of an operator.

---

### Synopsis

```
ALTER OPERATOR name ( {lefttype | NONE} , {righttype | NONE} )
OWNER TO newowner
```

---

### Description

ALTER OPERATOR changes the definition of an operator. The only currently available functionality is to change the owner of the operator.

You must own the operator to use ALTER OPERATOR. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the operator's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator. However, a superuser can alter ownership of any operator anyway.)

---

### Parameters

#### *name*

The name (optionally schema-qualified) of an existing operator.

#### *lefttype*

The data type of the operator's left operand; write NONE if the operator has no left operand.

#### *righttype*

The data type of the operator's right operand; write NONE if the operator has no right operand.

#### *newowner*

The new owner of the operator.

---

### Examples

Change the owner of a custom operator *a @@ b* for type *text*:

```
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

---

### Compatibility

There is no ALTER OPERATOR statement in the SQL standard.

---

### See Also

[CREATE OPERATOR](#), [DROP OPERATOR](#)

---

## ALTER OPERATOR CLASS

Changes the definition of an operator class.

---

### Synopsis

```
ALTER OPERATOR CLASS name USING index_method RENAME TO newname  
ALTER OPERATOR CLASS name USING index_method OWNER TO newowner
```

---

### Description

ALTER OPERATOR CLASS changes the definition of an operator class.

You must own the operator class to use ALTER OPERATOR CLASS. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the operator class's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator class. However, a superuser can alter ownership of any operator class anyway.)

---

### Parameters

#### *name*

The name (optionally schema-qualified) of an existing operator class.

#### *index\_method*

The name of the index method this operator class is for.

#### *newname*

The new name of the operator class.

#### *newowner*

The new owner of the operator class

---

### Compatibility

There is no ALTER OPERATOR CLASS statement in the SQL standard.

---

### See Also

[CREATE OPERATOR CLASS](#), [DROP OPERATOR CLASS](#)

---

## ALTER PROTOCOL

Changes the definition of a protocol.

---

### Synopsis

```
ALTER PROTOCOL name RENAME TO newname
```

```
ALTER PROTOCOL name OWNER TO newowner
```

---

### Description

ALTER PROTOCOL changes the definition of a protocol. Only the protocol name or owner can be altered.

You must own the protocol to use ALTER PROTOCOL. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on schema of the conversion.

These restrictions are in place to ensure that altering the owner only makes changes that could be made by dropping and recreating the protocol. Note that a superuser can alter ownership of any protocol.

---

### Parameters

***name***

The name (optionally schema-qualified) of an existing protocol.

***newname***

The new name of the protocol.

***newowner***

The new owner of the protocol.

---

### Examples

To rename the conversion *GPDBauth* to *GPDB\_authentication*:

```
ALTER PROTOCOL GPDBauth RENAME TO GPDB_authentication;
```

To change the owner of the conversion *GPDB\_authentication* to *joe*:

```
ALTER PROTOCOL GPDB_authentication OWNER TO joe;
```

---

### Compatibility

There is no ALTER PROTOCOL statement in the SQL standard.

---

## ALTER RESOURCE QUEUE

Changes the limits of a resource queue.

---

### Synopsis

```
ALTER RESOURCE QUEUE name WITH ( queue_attribute=value [, ... ] )
```

where *queue\_attribute* is:

```
ACTIVE_STATEMENTS=integer
MEMORY_LIMIT='memory_units'
MAX_COST=float
COST_OVERCOMMIT={TRUE|FALSE}
MIN_COST=float
PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}
```

```
ALTER RESOURCE QUEUE name WITHOUT ( queue_attribute [, ... ] )
```

where *queue\_attribute* is:

```
ACTIVE_STATEMENTS
MEMORY_LIMIT
MAX_COST
COST_OVERCOMMIT
MIN_COST
```

Note: A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

---

### Description

`ALTER RESOURCE QUEUE` changes the limits of a resource queue. Only a superuser can alter a resource queue. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). You can also set or reset priority for a resource queue to control the relative share of available CPU resources used by queries associated with the queue, or memory limit of a resource queue to control the amount of memory that all queries submitted through the queue can consume on a segment host.

`ALTER RESOURCE QUEUE WITHOUT` removes the specified limits on a resource that were previously set. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

---

### Parameters

***name***

The name of the resource queue whose limits are to be altered.

**ACTIVE\_STATEMENTS *integer***

The number of active statements submitted from users in this resource queue allowed on the system at any one time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0. To reset `ACTIVE_STATEMENTS` to have no limit, enter a value of -1.

**MEMORY\_LIMIT '*memory\_units*'**

Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum; however the upper boundary at query execution time is limited by the physical memory of a segment host. The default value is no limit (-1).

**MAX\_COST *float***

The total query planner cost of statements submitted from users in this resource queue allowed on the system at any one time. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MAX_COST` to have no limit, enter a value of -1.0.

**COST\_OVERCOMMIT *boolean***

If a resource queue is limited based on query cost, then the administrator can allow cost overcommit (`COST_OVERCOMMIT=TRUE`, the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

**MIN\_COST *float***

Queries with a cost under this limit will not be queued and run immediately. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MIN_COST` to have no limit, enter a value of -1.0.

**PRIORITY={*MIN* | *LOW* | *MEDIUM* | *HIGH* | *MAX*}**

Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are executed.

---

**Notes**

Use `CREATE ROLE` or `ALTER ROLE` to add a role (user) to a resource queue.

---

**Examples**

Change the active query limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Change the memory limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (MEMORY_LIMIT='2GB');
```

Reset the maximum and minimum query cost limit for a resource queue to no limit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0, MIN_COST=-1.0);
```

Reset the query cost limit for a resource queue to  $3^{10}$  (or 30000000000.0) and do not allow overcommit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10,
COST_OVERCOMMIT=FALSE);
```

Reset the priority of queries associated with a resource queue to the minimum level:

```
ALTER RESOURCE QUEUE myqueue WITH (PRIORITY=MIN);
```

Remove the MAX\_COST and MEMORY\_LIMIT limits from a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITHOUT (MAX_COST, MEMORY_LIMIT);
```

---

## Compatibility

The ALTER RESOURCE QUEUE statement is a Greenplum Database extension. This command does not exist in standard PostgreSQL.

---

## See Also

[CREATE RESOURCE QUEUE](#), [DROP RESOURCE QUEUE](#), [CREATE ROLE](#), [ALTER ROLE](#)

---

## ALTER ROLE

Changes a database role (user or group).

---

### Synopsis

```
ALTER ROLE name RENAME TO newname
ALTER ROLE name SET config_parameter {TO | =} {value | DEFAULT}
ALTER ROLE name RESET config_parameter
ALTER ROLE name RESOURCE QUEUE {queue_name | NONE}
ALTER ROLE name [ [WITH] option [ ... ] ]
```

where *option* can be:

```
    SUPERUSER | NOSUPERUSER
  | CREATEDB | NOCREATEDB
  | CREATEROLE | NOCREATEROLE
  | CREATEEXTTABLE | NOCREATEEXTTABLE
  | [ ( attribute='value'[, ...] ) ]
    where attributes and values are:
        type='readable' | 'writable'
        protocol='gpfdist' | 'http'
  | INHERIT | NOINHERIT
  | LOGIN | NOLOGIN
  | CONNECTION LIMIT conlimit
  | [ENCRYPTED | UNENCRYPTED] PASSWORD 'password'
  | VALID UNTIL 'timestamp'
  | [ DENY deny_point ]
  | [ DENY BETWEEN deny_point AND deny_point]
  | [ DROP DENY FOR deny_point ]
```

---

### Description

ALTER ROLE changes the attributes of a Greenplum Database role. There are several variants of this command:

- **RENAME** — Changes the name of the role. Database superusers can rename any role. Roles having CREATEROLE privilege can rename non-superuser roles. The current session user cannot be renamed (connect as a different user to rename a role). Because MD5-encrypted passwords use the role name as cryptographic salt, renaming a role clears its password if the password is MD5-encrypted.

- **SET | RESET** — changes a role’s session default for a specified configuration parameter. Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in server configuration file (`postgresql.conf`). For a role without `LOGIN` privilege, session defaults have no effect. Ordinary roles can change their own session defaults. Superusers can change anyone’s session defaults. Roles having `CREATEROLE` privilege can change defaults for non-superuser roles. See the *Greenplum Database Server Parameters Guide* for information about all user-settable configuration parameters.
- **RESOURCE QUEUE** — Assigns the role to a workload management resource queue. The role would then be subject to the limits assigned to the resource queue when issuing queries. Specify `NONE` to assign the role to the default resource queue. A role can only belong to one resource queue. For a role without `LOGIN` privilege, resource queues have no effect. See [CREATE RESOURCE QUEUE](#) for more information.
- **WITH option** — Changes many of the role attributes that can be specified in [CREATE ROLE](#). Attributes not mentioned in the command retain their previous settings. Database superusers can change any of these settings for any role. Roles having `CREATEROLE` privilege can change any of these settings, but only for non-superuser roles. Ordinary roles can only change their own password.

---

## Parameters

***name***

The name of the role whose attributes are to be altered.

***newname***

The new name of the role.

***config\_parameter=value***

Set this role’s session default for the specified configuration parameter to the given value. If value is `DEFAULT` or if `RESET` is used, the role-specific variable setting is removed, so the role will inherit the system-wide default setting in new sessions. Use `RESET ALL` to clear all role-specific settings. See [SET](#) and “[Server Configuration Parameters](#)” on page 476 for information about user-settable configuration parameters.

***queue\_name***

The name of the resource queue to which the user-level role is to be assigned. Only roles with `LOGIN` privilege can be assigned to a resource queue. To unassign a role from a resource queue and put it in the default resource queue, specify `NONE`. A role can only belong to one resource queue.

**SUPERUSER | NOSUPERUSER**  
**CREATEDB | NOCREATEDB**

**CREATEROLE** | **NOCREATEROLE**  
**CREATEEXTTABLE** | **NOCREATEEXTTABLE** [(*attribute*=*value*)]

If **CREATEEXTTABLE** is specified, the role being defined is allowed to create external tables. The default type is *readable* and the default protocol is *gpfdist* if not specified. **NOCREATEEXTTABLE** (the default) denies the role the ability to create external tables. Note that external tables that use the *file* or *execute* protocols can only be created by superusers.

**INHERIT** | **NOINHERIT**  
**LOGIN** | **NOLOGIN**  
**CONNECTION LIMIT** *conlimit*  
**PASSWORD** *password*  
**ENCRYPTED** | **UNENCRYPTED**  
**VALID UNTIL** '*timestamp*'

These clauses alter role attributes originally set by [CREATE ROLE](#).

**DENY** *deny\_point*  
**DENY BETWEEN** *deny\_point* **AND** *deny\_point*

The **DENY** and **DENY BETWEEN** keywords set time-based constraints that are enforced at login. **DENY** sets a day or a day and time to deny access. **DENY BETWEEN** sets an interval during which access is denied. Both use the parameter *deny\_point* that has following format:

DAY *day* [ TIME '*time*' ]

The two parts of the *deny\_point* parameter use the following formats:

For day:

{ '*Sunday*' | '*Monday*' | '*Tuesday*' | '*Wednesday*' | '*Thursday*' | '*Friday*' | '*Saturday*' | 0-6 }

For time:

{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM } }

The **DENY BETWEEN** clause uses two *deny\_point* parameters.

**DENY BETWEEN** *deny\_point* **AND** *deny\_point*

For more information about time-based constraints and examples, see the Greenplum Database Database Administrator Guide.

**DROP DENY FOR** *deny\_point*

The **DROP DENY FOR** clause removes a time-based constraint from the role. It uses the *deny\_point* parameter described above.

For more information on removing a time-based constraint and examples, see the Greenplum Database Database Administrator Guide.

---

## Notes

Use [GRANT](#) and [REVOKE](#) for adding and removing role memberships.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear text, and it might also be logged in the client's command history or the server log. The `psql` command-line client contains a meta-command `\password` that can be used to safely change a role's password.

It is also possible to tie a session default to a specific database rather than to a role. Role-specific settings override database-specific ones if there is a conflict. See [ALTER DATABASE](#).

---

## Examples

Change the password for a role:

```
ALTER ROLE daria WITH PASSWORD 'passwd123';
```

Change a password expiration date:

```
ALTER ROLE scott VALID UNTIL 'May 4 12:00:00 2015 +1';
```

Make a password valid forever:

```
ALTER ROLE luke VALID UNTIL 'infinity';
```

Give a role the ability to create other roles and new databases:

```
ALTER ROLE joelle CREATEROLE CREATEDB;
```

Give a role a non-default setting of the *maintenance\_work\_mem* parameter:

```
ALTER ROLE admin SET maintenance_work_mem = 100000;
```

Assign a role to a resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

Give a role permission to create writable external tables:

```
ALTER ROLE load CREATEEXTTABLE (type='writable');
```

Alter a role so it does not allow login access on Sundays:

```
ALTER ROLE user3 DENY DAY 'Sunday';
```

Alter a role to remove the constraint that does not allow login access on Sundays:

```
ALTER ROLE user3 DROP DENY FOR DAY 'Sunday';
```

---

## Compatibility

The `ALTER ROLE` statement is a Greenplum Database extension.

---

## See Also

---

## ALTER SCHEMA

Changes the definition of a schema.

---

### Synopsis

```
ALTER SCHEMA name RENAME TO newname
```

```
ALTER SCHEMA name OWNER TO newowner
```

---

### Description

ALTER SCHEMA changes the definition of a schema.

You must own the schema to use ALTER SCHEMA. To rename a schema you must also have the CREATE privilege for the database. To alter the owner, you must also be a direct or indirect member of the new owning role, and you must have the CREATE privilege for the database. Note that superusers have all these privileges automatically.

---

### Parameters

***name***

The name of an existing schema.

***newname***

The new name of the schema. The new name cannot begin with pg\_, as such names are reserved for system schemas.

***newowner***

The new owner of the schema.

---

### Compatibility

There is no ALTER SCHEMA statement in the SQL standard.

---

### See Also

[CREATE SCHEMA](#), [DROP SCHEMA](#)

---

## ALTER SEQUENCE

Changes the definition of a sequence generator.

---

### Synopsis

```
ALTER SEQUENCE name [INCREMENT [ BY ] increment]
    [MINVALUE minvalue | NO MINVALUE]
    [MAXVALUE maxvalue | NO MAXVALUE]
    [RESTART [ WITH ] start]
    [CACHE cache] [[ NO ] CYCLE]
    [OWNED BY {table.column | NONE}]

ALTER SEQUENCE name SET SCHEMA new_schema
```

---

### Description

ALTER SEQUENCE changes the parameters of an existing sequence generator. Any parameters not specifically set in the ALTER SEQUENCE command retain their prior settings.

You must own the sequence to use ALTER SEQUENCE. To change a sequence's schema, you must also have CREATE privilege on the new schema. Note that superusers have all these privileges automatically.

---

### Parameters

#### *name*

The name (optionally schema-qualified) of a sequence to be altered.

#### *increment*

The clause INCREMENT BY *increment* is optional. A positive value will make an ascending sequence, a negative one a descending sequence. If unspecified, the old increment value will be maintained.

#### *minvalue* NO MINVALUE

The optional clause MINVALUE *minvalue* determines the minimum value a sequence can generate. If NO MINVALUE is specified, the defaults of 1 and -263-1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current minimum value will be maintained.

#### *maxvalue* NO MAXVALUE

The optional clause MAXVALUE *maxvalue* determines the maximum value for the sequence. If NO MAXVALUE is specified, the defaults are 263-1 and -1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current maximum value will be maintained.

***start***

The optional clause `RESTART WITH start` changes the current value of the sequence.

***cache***

The clause `CACHE cache` enables sequence numbers to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache). If unspecified, the old cache value will be maintained.

**CYCLE**

The optional `CYCLE` key word may be used to enable the sequence to wrap around when the *maxvalue* or *minvalue* has been reached by an ascending or descending sequence. If the limit is reached, the next number generated will be the respective *minvalue* or *maxvalue*.

**NO CYCLE**

If the optional `NO CYCLE` key word is specified, any calls to `nextval` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, the old cycle behavior will be maintained.

**OWNED BY *table.column*****OWNED BY NONE**

The `OWNED BY` option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. If specified, this association replaces any previously specified association for the sequence. The specified table must have the same owner and be in the same schema as the sequence. Specifying `OWNED BY NONE` removes any existing table column association.

***new\_schema***

The new schema for the sequence.

---

**Notes**

To avoid blocking of concurrent transactions that obtain numbers from the same sequence, `ALTER SEQUENCE`'s effects on the sequence generation parameters are never rolled back; those changes take effect immediately and are not reversible. However, the `OWNED BY` and `SET SCHEMA` clauses are ordinary catalog updates and can be rolled back.

`ALTER SEQUENCE` will not immediately affect `nextval` results in sessions, other than the current one, that have preallocated (cached) sequence values. They will use up all cached values prior to noticing the changed sequence generation parameters. The current session will be affected immediately.

Some variants of `ALTER TABLE` can be used with sequences as well. For example, to rename a sequence use `ALTER TABLE RENAME`.

---

## Examples

Restart a sequence called *serial*, at 105:

```
ALTER SEQUENCE serial RESTART WITH 105;
```

---

## Compatibility

ALTER SEQUENCE conforms to the SQL standard, except for the OWNED BY and SET SCHEMA clauses, which are Greenplum Database extensions.

---

## ALTER TABLE

Changes the definition of a table.

### Synopsis

```
ALTER TABLE [ONLY] name RENAME [COLUMN] column TO new_column
```

```
ALTER TABLE name RENAME TO new_name
```

```
ALTER TABLE name SET SCHEMA new_schema
```

```
ALTER TABLE [ONLY] name SET
    DISTRIBUTED BY (column, [ ... ] )
    | DISTRIBUTED RANDOMLY
    | WITH (REORGANIZE=true|false)
```

```
ALTER TABLE [ONLY] name action [, ... ]
```

```
ALTER TABLE name
    [ ALTER PARTITION { partition_name | FOR (RANK(number))
                        | FOR (value) } partition_action [...] ]
    partition_action
```

where *action* is one of:

```
ADD [COLUMN] column_name type
    [column_constraint [ ... ] ]
DROP [COLUMN] column [RESTRICT | CASCADE]
ALTER [COLUMN] column TYPE type [USING expression]
ALTER [COLUMN] column SET DEFAULT expression
ALTER [COLUMN] column DROP DEFAULT
ALTER [COLUMN] column { SET | DROP } NOT NULL
ALTER [COLUMN] column SET STATISTICS integer
ADD table_constraint
DROP CONSTRAINT constraint_name [RESTRICT | CASCADE]
DISABLE TRIGGER [trigger_name | ALL | USER]
ENABLE TRIGGER [trigger_name | ALL | USER]
CLUSTER ON index_name
SET WITHOUT CLUSTER
SET WITHOUT OIDS
SET (FILLFACTOR = value)
RESET (FILLFACTOR)
INHERIT parent_table
NO INHERIT parent_table
OWNER TO new_owner
SET TABLESPACE new_tablespace
```

where *partition\_action* is one of:

```
ALTER DEFAULT PARTITION
DROP DEFAULT PARTITION [IF EXISTS]
DROP PARTITION [IF EXISTS] { partition_name |
    FOR (RANK(number)) | FOR (value) } [CASCADE]
```

```

TRUNCATE DEFAULT PARTITION
TRUNCATE PARTITION { partition_name | FOR (RANK(number)) |
    FOR (value) }
RENAME DEFAULT PARTITION TO new_partition_name
RENAME PARTITION { partition_name | FOR (RANK(number)) |

| [SUBPARTITION subpartition_name]
  START ([datatype] 'start_value') [INCLUSIVE | EXCLUSIVE]
  [ END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE] ]
  [ EVERY ( [number / datatype] 'interval_value') ]
| [SUBPARTITION subpartition_name]
  END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE]
  [ EVERY ( [number / datatype] 'interval_value') ]

```

```
[ WITH ( partition_storage_parameter=value [, ... ] ) ]
[ TABLESPACE tablespace ]
```

where *storage\_parameter* is:

```
APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
COMPRESSTYPE={ZLIB|QUICKLZ|NONE}
COMPRESSLEVEL={0-9}
FILLFACTOR={10-100}
OIDS [=TRUE|FALSE]
```

---

## Description

**ALTER TABLE** changes the definition of an existing table. There are several subforms:

- **ADD COLUMN** — Adds a new column to the table, using the same syntax as **CREATE TABLE**. **DROP COLUMN** — Drops a column from a table. Note that if you drop table columns that are being used as the Greenplum Database distribution key, the distribution policy for the table will be changed to **DISTRIBUTED RANDOMLY**. Indexes and table constraints involving the column will be automatically dropped as well. You will need to say **CASCADE** if anything outside the table depends on the column (such as views).
- **ALTER COLUMN TYPE** — Changes the data type of a column of a table. Note that you cannot alter column data types that are being used as distribution or partitioning keys. Indexes and simple table constraints involving the column will be automatically converted to use the new column type by reparsing the originally supplied expression. The optional **USING** clause specifies how to compute the new column value from the old. If omitted, the default conversion is the same as an assignment cast from old data type to new. A **USING** clause must be provided if there is no implicit or assignment cast from old to new type.
- **SET/DROP DEFAULT** — Sets or removes the default value for a column. The default values only apply to subsequent **INSERT** commands. They do not cause rows already in the table to change. Defaults may also be created for views, in which case they are inserted into statements on the view before the view's **ON INSERT** rule is applied.
- **SET/DROP NOT NULL** — Changes whether a column is marked to allow null values or to reject null values. You can only use **SET NOT NULL** when the column contains no null values.
- **SET STATISTICS** — Sets the per-column statistics-gathering target for subsequent **ANALYZE** operations. The target can be set in the range 0 to 1000, or set to -1 to revert to using the system default statistics target (`default_statistics_target`).
- **ADD table\_constraint** — Adds a new constraint to a table (not just a partition) using the same syntax as **CREATE TABLE**.
- **DROP CONSTRAINT** — Drops the specified constraint on a table.

- **DISABLE/ENABLE TRIGGER** — Disables or enables trigger(s) belonging to the table. A disabled trigger is still known to the system, but is not executed when its triggering event occurs. For a deferred trigger, the enable status is checked when the event occurs, not when the trigger function is actually executed. One may disable or enable a single trigger specified by name, or all triggers on the table, or only user-created triggers. Disabling or enabling constraint triggers requires superuser privileges. Note that foreign key constraint triggers are not currently supported in Greenplum Database, and triggers in general have very limited functionality due to the parallelism of Greenplum Database. See `CREATE TRIGGER` for more information.
- **CLUSTER/SET WITHOUT CLUSTER** — Selects or removes the default index for future `CLUSTER` operations. It does not actually re-cluster the table. Note that `CLUSTER` is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with `CREATE TABLE AS` and order it by the index column(s).
- **SET WITHOUT OIDS** — Removes the OID system column from the table. Note that there is no variant of `ALTER TABLE` that allows OIDs to be restored to a table once they have been removed.
- **SET ( FILLFACTOR = value) / RESET (FILLFACTOR)** — Changes the fillfactor for the table. The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, `INSERT` operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives `UPDATE` a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate. Note that the table contents will not be modified immediately by this command. You will need to rewrite the table to get the desired effects.
- **SET DISTRIBUTED** — Changes the distribution policy of a table. Changes to a hash distribution policy will cause the table data to be physically redistributed on disk, which can be resource intensive.
- **INHERIT parent\_table / NO INHERIT parent\_table** — Adds or removes the target table as a child of the specified parent table. Queries against the parent will include records of its child table. To be added as a child, the target table must already contain all the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have `NOT NULL` constraints in the parent then they must also have `NOT NULL` constraints in the child. There must also be matching child-table constraints for all `CHECK` constraints of the parent.
- **OWNER** — Changes the owner of the table, sequence, or view to the specified user.
- **SET TABLESPACE** — Changes the table's tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the table, if any, are not moved; but they can be moved separately with additional `SET TABLESPACE` commands. See also `CREATE TABLESPACE`. If changing the tablespace of a partitioned table, all child table partitions will also be moved to the new tablespace.

- **RENAME** — Changes the name of a table (or an index, sequence, or view) or the name of an individual column in a table. There is no effect on the stored data. Note that Greenplum Database distribution key columns cannot be renamed.
- **SET SCHEMA** — Moves the table into another schema. Associated indexes, constraints, and sequences owned by table columns are moved as well.
- **ALTER PARTITION | DROP PARTITION | RENAME PARTITION | TRUNCATE PARTITION | ADD PARTITION | SPLIT PARTITION | EXCHANGE PARTITION | SET SUBPARTITION TEMPLATE** — Changes the structure of a partitioned table. In most cases, you must go through the parent table to alter one of its child table partitions.

**Note:** If you add a partition to a table that has subpartition encodings, the new partition inherits the storage directives for the subpartitions. For more information about the precedence of compression settings, see the *Greenplum Database Database Administrator Guide*.

You must own the table to use `ALTER TABLE`. To change the schema of a table, you must also have `CREATE` privilege on the new schema. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the table's schema. A superuser has these privileges automatically.

**Note:** Memory usage increases significantly when a table has many partitions, if a table has compression, or if the blocksize for a table is large. If the number of relations associated with the table is large, this condition can force an operation on the table to use more memory. For example, if the table is a CO table and has a large number of columns, each column is a relation. An operation like `ALTER TABLE ALTER COLUMN` opens all the columns in the table allocates associated buffers. If a CO table has 40 columns and 100 partitions, and the columns are compressed and the blocksize is 2 MB (with a system factor of 3), the system attempts to allocate 24 GB, that is  $(40 \times 100) \times (2 \times 3)$  MB or 24 GB.

---

## Parameters

### ONLY

Only perform the operation on the table name specified. If the `ONLY` keyword is not used, the operation will be performed on the named table and any child table partitions associated with that table.

### name

The name (possibly schema-qualified) of an existing table to alter. If `ONLY` is specified, only that table is altered. If `ONLY` is not specified, the table and all its descendant tables (if any) are updated.

**Note:** Constraints can only be added to an entire table, not to a partition. Because of that restriction, the *name* parameter can only contain a table name, not a partition name.

***column***

Name of a new or existing column. Note that Greenplum Database distribution key columns must be treated with special care. Altering or dropping these columns can change the distribution policy for the table.

***new\_column***

New name for an existing column.

***new\_name***

New name for the table.

***type***

Data type of the new column, or new data type for an existing column. If changing the data type of a Greenplum distribution key column, you are only allowed to change it to a compatible type (for example, `text` to `varchar` is OK, but `text` to `int` is not).

***table\_constraint***

New table constraint for the table. Note that foreign key constraints are currently not supported in Greenplum Database. Also a table is only allowed one unique constraint and the uniqueness must be within the Greenplum Database distribution key.

***constraint\_name***

Name of an existing constraint to drop.

**CASCADE**

Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column).

**RESTRICT**

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

***trigger\_name***

Name of a single trigger to disable or enable. Note that Greenplum Database has limited support of triggers. See `CREATE TRIGGER` for more information.

**ALL**

Disable or enable all triggers belonging to the table including constraint related triggers. This requires superuser privilege.

**USER**

Disable or enable all user-created triggers belonging to the table.

***index\_name***

The index name on which the table should be marked for clustering. Note that `CLUSTER` is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with `CREATE TABLE AS` and order it by the index column(s).

**FILLFACTOR**

Set the fillfactor percentage for a table.

***value***

The new value for the `FILLFACTOR` parameter, which is a percentage between 10 and 100. 100 is the default.

**DISTRIBUTED BY (*column*) | DISTRIBUTED RANDOMLY**

Specifies the distribution policy for a table. Changing a hash distribution policy will cause the table data to be physically redistributed on disk, which can be resource intensive. If you declare the same hash distribution policy or change from hash to random distribution, data will not be redistributed unless you declare `SET WITH (REORGANIZE=true)`.

**REORGANIZE=true | false**

Use `REORGANIZE=true` when the hash distribution policy has not changed or when you have changed from a hash to a random distribution, and you want to redistribute the data anyways.

***parent\_table***

A parent table to associate or de-associate with this table.

***new\_owner***

The role name of the new owner of the table.

***new\_tablespace***

The name of the tablespace to which the table will be moved.

***new\_schema***

The name of the schema to which the table will be moved.

***parent\_table\_name***

When altering a partitioned table, the name of the top-level parent table.

**ALTER [DEFAULT] PARTITION**

If altering a partition deeper than the first level of partitions, the `ALTER PARTITION` clause is used to specify which subpartition in the hierarchy you want to alter.

**DROP [DEFAULT] PARTITION**

Drops the specified partition. If the partition has subpartitions, the subpartitions are automatically dropped as well.

**TRUNCATE [DEFAULT] PARTITION**

Truncates the specified partition. If the partition has subpartitions, the subpartitions are automatically truncated as well.

**RENAME [DEFAULT] PARTITION**

Changes the partition name of a partition (not the relation name). Partitioned tables are created using the naming convention:

*<parentname>\_<level>\_prt\_<partition\_name>.*

**ADD DEFAULT PARTITION**

Adds a default partition to an existing partition design. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition. Default partitions must be given a name.

**ADD PARTITION**

***partition\_element*** - Using the existing partition type of the table (range or list), defines the boundaries of new partition you are adding.

***name*** - A name for this new partition.

**VALUES** - For list partitions, defines the value(s) that the partition will contain.

**START** - For range partitions, defines the starting range value for the partition. By default, start values are **INCLUSIVE**. For example, if you declared a start date of '2008-01-01', then the partition would contain all dates greater than or equal to '2008-01-01'. Typically the data type of the **START** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**END** - For range partitions, defines the ending range value for the partition. By default, end values are **EXCLUSIVE**. For example, if you declared an end date of '2008-02-01', then the partition would contain all dates less than but not equal to '2008-02-01'. Typically the data type of the **END** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**WITH** - Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables. See [CREATE TABLE](#) for a description of the storage options.

**TABLESPACE** - The name of the tablespace in which the partition is to be created.

***subpartition\_spec*** - Only allowed on partition designs that were created without a subpartition template. Declares a subpartition specification for the new partition you are adding. If the partitioned table was originally defined using a subpartition template, then the template will be used to generate the subpartitions automatically.

**EXCHANGE [DEFAULT] PARTITION**

Exchanges another table into the partition hierarchy into the place of an existing partition. In a multi-level partition design, you can only exchange the lowest level partitions (those that contain data).

**WITH TABLE *table\_name*** - The name of the table you are swapping in to the partition design.

**WITH | WITHOUT VALIDATION** - Validates that the data in the table matches the CHECK constraint of the partition you are exchanging. The default is to validate the data against the CHECK constraint.

**SET SUBPARTITION TEMPLATE**

Modifies the subpartition template for an existing partition. After a new subpartition template is set, all new partitions added will have the new subpartition design (existing partitions are not modified).

**SPLIT DEFAULT PARTITION**

Splits a default partition. In a multi-level partition design, you can only split the lowest level default partitions (those that contain data). Splitting a default partition creates a new partition containing the values specified and leaves the default partition containing any values that do not match to an existing partition.

**AT** - For list partitioned tables, specifies a single list value that should be used as the criteria for the split.

**START** - For range partitioned tables, specifies a starting value for the new partition.

**END** - For range partitioned tables, specifies an ending value for the new partition.

**INTO** - Allows you to specify a name for the new partition. When using the INTO clause to split a default partition, the second partition name specified should always be that of the existing default partition. If you do not know the name of the default partition, you can look it up using the *pg\_partitions* view.

**SPLIT PARTITION**

Splits an existing partition into two partitions. In a multi-level partition design, you can only split the lowest level partitions (those that contain data).

**AT** - Specifies a single value that should be used as the criteria for the split. The partition will be divided into two new partitions with the split value specified being the starting range for the *latter* partition.

**INTO** - Allows you to specify names for the two new partitions created by the split.

***partition\_name***

The given name of a partition.

**FOR (RANK (*number*))**

For range partitions, the rank of the partition in the range.

**FOR ('value')**

Specifies a partition by declaring a value that falls within the partition boundary specification. If the value declared with **FOR** matches to both a partition and one of its subpartitions (for example, if the value is a date and the table is partitioned by month and then by day), then **FOR** will operate on the first level where a match is found (for example, the monthly partition). If your intent is to operate on a subpartition, you must declare so as follows:

```
ALTER TABLE name ALTER PARTITION FOR ('2008-10-01') DROP
PARTITION FOR ('2008-10-01');
```

---

**Notes**

Take special care when altering or dropping columns that are part of the Greenplum Database distribution key as this can change the distribution policy for the table.

Greenplum Database does not currently support foreign key constraints. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not **DISTRIBUTED RANDOMLY**), and all of the distribution key columns must be the same as the initial columns of the unique constraint columns.

**Note:** The table name specified in the **ALTER TABLE** command cannot be the name of a partition within a table.

Adding a **CHECK** or **NOT NULL** constraint requires scanning the table to verify that existing rows meet the constraint.

When a column is added with **ADD COLUMN**, all existing rows in the table are initialized with the column's default value (**NULL** if no **DEFAULT** clause is specified). Adding a column with a non-null default or changing the type of an existing column will require the entire table to be rewritten. This may take a significant amount of time for a large table; and it will temporarily require double the disk space.

You can specify multiple changes in a single **ALTER TABLE** command, which will be done in a single pass over the table.

The **DROP COLUMN** form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated.

The fact that **ALTER TYPE** requires rewriting the whole table is sometimes an advantage, because the rewriting process eliminates any dead space in the table. For example, to reclaim the space occupied by a dropped column immediately, the fastest way is: **ALTER TABLE table ALTER COLUMN anycol TYPE sametype;** Where *anycol* is any remaining table column and *sametype* is the same type that column already has. This results in no semantically-visible change in the table, but the command forces rewriting, which gets rid of no-longer-useful data.

If a table is partitioned or has any descendant tables, it is not permitted to add, rename, or change the type of a column in the parent table without doing the same to the descendants. This ensures that the descendants always have columns matching the parent.

To see the structure of a partitioned table, you can use the view *pg\_partitions*. This view can help identify the particular partitions you may want to alter.

A recursive `DROP COLUMN` operation will remove a descendant table's column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive `DROP COLUMN (ALTER TABLE ONLY ... DROP COLUMN)` never removes any descendant columns, but instead marks them as independently defined rather than inherited.

The `TRIGGER`, `CLUSTER`, `OWNER`, and `TABLESPACE` actions never recurse to descendant tables; that is, they always act as though `ONLY` were specified. Adding a constraint can recurse only for `CHECK` constraints.

Changing any part of a system catalog table is not permitted.

---

## Examples

Add a column to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

Rename an existing column:

```
ALTER TABLE distributors RENAME COLUMN address TO city;
```

Rename an existing table:

```
ALTER TABLE distributors RENAME TO suppliers;
```

Add a not-null constraint to a column:

```
ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;
```

Add a check constraint to a table:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK
(char_length(zipcode) = 5);
```

Move a table to a different schema:

```
ALTER TABLE myschema.distributors SET SCHEMA yourschema;
```

Add a new partition to a partitioned table:

```
ALTER TABLE sales ADD PARTITION
    START (date '2009-02-01') INCLUSIVE
    END (date '2009-03-01') EXCLUSIVE;
```

Add a default partition to an existing partition design:

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

Rename a partition:

```
ALTER TABLE sales RENAME PARTITION FOR ('2008-01-01') TO
jan08;
```

Drop the first (oldest) partition in a range sequence:

```
ALTER TABLE sales DROP PARTITION FOR (RANK(1));
```

Exchange a table into your partition design:

```
ALTER TABLE sales EXCHANGE PARTITION FOR ('2008-01-01') WITH
TABLE jan08;
```

Split the default partition (where the existing default partition's name is *'other'*) to add a new monthly partition for January 2009:

```
ALTER TABLE sales SPLIT DEFAULT PARTITION
START ('2009-01-01') INCLUSIVE
END ('2009-02-01') EXCLUSIVE
INTO (PARTITION jan09, PARTITION other);
```

Split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```
ALTER TABLE sales SPLIT PARTITION FOR ('2008-01-01')
AT ('2008-01-16')
INTO (PARTITION jan081to15, PARTITION jan0816to31);
```

---

## Compatibility

The ADD, DROP, and SET DEFAULT forms conform with the SQL standard. The other forms are Greenplum Database extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single ALTER TABLE command is an extension.

ALTER TABLE DROP COLUMN can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

---

## See Also

[CREATE TABLE](#), [DROP TABLE](#)

---

## ALTER TABLESPACE

Changes the definition of a tablespace.

---

### Synopsis

```
ALTER TABLESPACE name RENAME TO newname
```

```
ALTER TABLESPACE name OWNER TO newowner
```

---

### Description

ALTER TABLESPACE changes the definition of a tablespace.

You must own the tablespace to use ALTER TABLESPACE. To alter the owner, you must also be a direct or indirect member of the new owning role. (Note that superusers have these privileges automatically.)

---

### Parameters

***name***

The name of an existing tablespace.

***newname***

The new name of the tablespace. The new name cannot begin with *pg\_* or *gp\_* (reserved for system tablespaces).

***newowner***

The new owner of the tablespace.

---

### Examples

Rename tablespace *index\_space* to *fast\_raid*:

```
ALTER TABLESPACE index_space RENAME TO fast_raid;
```

Change the owner of tablespace *index\_space*:

```
ALTER TABLESPACE index_space OWNER TO mary;
```

---

### Compatibility

There is no ALTER TABLESPACE statement in the SQL standard.

---

### See Also

[CREATE TABLESPACE](#), [DROP TABLESPACE](#)

---

## ALTER TRIGGER

Changes the definition of a trigger.

---

### Synopsis

```
ALTER TRIGGER name ON table RENAME TO newname
```

---

### Description

`ALTER TRIGGER` changes properties of an existing trigger. The `RENAME` clause changes the name of the given trigger without otherwise changing the trigger definition. You must own the table on which the trigger acts to be allowed to change its properties.

---

### Parameters

***name***

The name of an existing trigger to alter.

***table***

The name of the table on which this trigger acts.

***newname***

The new name for the trigger.

---

### Notes

The ability to temporarily enable or disable a trigger is provided by [ALTER TABLE](#), not by `ALTER TRIGGER`, because `ALTER TRIGGER` has no convenient way to express the option of enabling or disabling all of a table's triggers at once.

Note that Greenplum Database has limited support of triggers in this release. See [CREATE TRIGGER](#) for more information.

---

### Examples

To rename an existing trigger:

```
ALTER TRIGGER emp_stamp ON emp RENAME TO emp_track_chgs;
```

---

### Compatibility

`ALTER TRIGGER` is a Greenplum Database extension of the SQL standard.

---

### See Also

[ALTER TABLE](#), [CREATE TRIGGER](#), [DROP TRIGGER](#)

---

## ALTER TYPE

Changes the definition of a data type.

---

### Synopsis

```
ALTER TYPE name  
        OWNER TO new_owner / SET SCHEMA new_schema
```

---

### Description

`ALTER TYPE` changes the definition of an existing type. You can change the owner and the schema of a type.

You must own the type to use `ALTER TYPE`. To change the schema of a type, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the type's schema. (These restrictions enforce that altering the owner does not do anything that could be done by dropping and recreating the type. However, a superuser can alter ownership of any type.)

---

### Parameters

#### *name*

The name (optionally schema-qualified) of an existing type to alter.

#### *new\_owner*

The user name of the new owner of the type.

#### *new\_schema*

The new schema for the type.

---

### Examples

To change the owner of the user-defined type *email* to *joe*:

```
ALTER TYPE email OWNER TO joe;
```

To change the schema of the user-defined type *email* to *customers*:

```
ALTER TYPE email SET SCHEMA customers;
```

---

### Compatibility

There is no `ALTER TYPE` statement in the SQL standard.

---

### See Also

[CREATE TYPE](#), [DROP TYPE](#)

---

## ALTER USER

Changes the definition of a database role (user).

---

### Synopsis

```
ALTER USER name RENAME TO newname
```

```
ALTER USER name SET config_parameter {TO | =} {value | DEFAULT}
```

```
ALTER USER name RESET config_parameter
```

```
ALTER USER name [ [WITH] option [ ... ] ]
```

where *option* can be:

```

SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'

```

---

### Description

ALTER USER is a deprecated command but is still accepted for historical reasons. It is an alias for ALTER ROLE. See [ALTER ROLE](#) for more information.

---

### Compatibility

The ALTER USER statement is a Greenplum Database extension. The SQL standard leaves the definition of users to the implementation.

---

### See Also

[ALTER ROLE](#)

---

## ANALYZE

Collects statistics about a database.

---

### Synopsis

```
ANALYZE [VERBOSE] [table [ (column [, ...] ) ]]
```

---

### Description

**ANALYZE** collects statistics about the contents of tables in the database, and stores the results in the system table *pg\_statistic*. Subsequently, the query planner uses these statistics to help determine the most efficient execution plans for queries.

With no parameter, **ANALYZE** examines every table in the current database. With a parameter, **ANALYZE** examines only that table. It is further possible to give a list of column names, in which case only the statistics for those columns are collected.

---

### Parameters

#### **VERBOSE**

Enables display of progress messages. When specified, **ANALYZE** emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

#### ***table***

The name (possibly schema-qualified) of a specific table to analyze. Defaults to all tables in the current database.

#### ***column***

The name of a specific column to analyze. Defaults to all columns.

---

### Notes

It is a good idea to run **ANALYZE** periodically, or just after making major changes in the contents of a table. Accurate statistics will help the query planner to choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy is to run **VACUUM** and **ANALYZE** once a day during a low-usage time of day.

**ANALYZE** requires only a read lock on the target table, so it can run in parallel with other activity on the table.

For partitioned tables, **ANALYZE** produces statistics at the root partition. **ANALYZE** on an individual partition of a partitioned table is not supported.

The statistics collected by `ANALYZE` usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these may be omitted if `ANALYZE` deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators.

For large tables, `ANALYZE` takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time `ANALYZE` is run, even if the actual table contents did not change. This may result in small changes in the planner's estimated costs shown by `EXPLAIN`. In rare situations, this non-determinism will cause the query optimizer to choose a different query plan between runs of `ANALYZE`. To avoid this, raise the amount of statistics collected by `ANALYZE` by adjusting the *default\_statistics\_target* configuration parameter, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET STATISTICS` (see `ALTER TABLE`). The target value sets the maximum number of entries in the most-common-value list and the maximum number of bins in the histogram. The default target value is 10, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for `ANALYZE` and the amount of space occupied in *pg\_statistic*. In particular, setting the statistics target to zero disables collection of statistics for that column. It may be useful to do that for columns that are never used as part of the `WHERE`, `GROUP BY`, or `ORDER BY` clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do `ANALYZE`.

---

## Examples

Collect statistics for the table *mytable*:

```
ANALYZE mytable;
```

---

## Compatibility

There is no `ANALYZE` statement in the SQL standard.

---

## See Also

[ALTER TABLE](#), [EXPLAIN](#), [VACUUM](#)

---

## BEGIN

Starts a transaction block.

---

### Synopsis

```
BEGIN [WORK | TRANSACTION] [transaction_mode] [READ ONLY | READ  
WRITE]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL | {SERIALIZABLE | REPEATABLE READ | READ  
COMMITTED | READ UNCOMMITTED}
```

---

### Description

BEGIN initiates a transaction block, that is, all statements after a BEGIN command will be executed in a single transaction until an explicit COMMIT or ROLLBACK is given. By default (without BEGIN), Greenplum Database executes transactions in autocommit mode, that is, each statement is executed in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).

Statements are executed more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if [SET TRANSACTION](#) was executed.

---

### Parameters

**WORK**  
**TRANSACTION**

Optional key words. They have no effect.

**SERIALIZABLE**  
**REPEATABLE READ**  
**READ COMMITTED**  
**READ UNCOMMITTED**

The SQL standard defines four transaction isolation levels: READ COMMITTED, READ UNCOMMITTED, SERIALIZABLE, and REPEATABLE READ. The default behavior is that a statement can only see rows committed before it began (READ COMMITTED). In Greenplum Database READ UNCOMMITTED is treated the same as READ COMMITTED. SERIALIZABLE is supported the same as REPEATABLE READ wherein all statements of the current transaction can only see rows committed before the first statement was executed in the transaction. SERIALIZABLE is the strictest transaction isolation.

This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. Applications using this level must be prepared to retry transactions due to serialization failures.

#### **READ WRITE**

#### **READ ONLY**

Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would execute is among those listed.

---

### **Notes**

`START TRANSACTION` has the same functionality as `BEGIN`.

Use `COMMIT` or `ROLLBACK` to terminate a transaction block.

Issuing `BEGIN` when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (see `SAVEPOINT`).

---

### **Examples**

To begin a transaction block:

```
BEGIN;
```

To begin a transaction block with the serializable isolation level:

```
BEGIN TRANSACTION ISOLATION LEVEL SERIALIZABLE;
```

---

### **Compatibility**

`BEGIN` is a Greenplum Database language extension. It is equivalent to the SQL-standard command `START TRANSACTION`.

Incidentally, the `BEGIN` key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

---

### **See Also**

`COMMIT`, `ROLLBACK`, `START TRANSACTION`, `SAVEPOINT`

---

## CHECKPOINT

Forces a transaction log checkpoint.

---

### Synopsis

CHECKPOINT

---

### Description

Write-Ahead Logging (WAL) puts a checkpoint in the transaction log every so often. The automatic checkpoint interval is set per Greenplum Database segment instance by the server configuration parameters *checkpoint\_segments* and *checkpoint\_timeout*. The `CHECKPOINT` command forces an immediate checkpoint when the command is issued, without waiting for a scheduled checkpoint.

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk.

Only superusers may call `CHECKPOINT`. The command is not intended for use during normal operation.

---

### Compatibility

The `CHECKPOINT` command is a Greenplum Database language extension.

---

## CLOSE

Closes a cursor.

---

### Synopsis

```
CLOSE cursor_name
```

---

### Description

`CLOSE` frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by `COMMIT` or `ROLLBACK`. A holdable cursor is implicitly closed if the transaction that created it aborts via `ROLLBACK`. If the creating transaction successfully commits, the holdable cursor remains open until an explicit `CLOSE` is executed, or the client disconnects.

---

### Parameters

*cursor\_name*

The name of an open cursor to close.

---

### Notes

Greenplum Database does not have an explicit `OPEN` cursor statement. A cursor is considered open when it is declared. Use the `DECLARE` statement to declare (and open) a cursor.

You can see all available cursors by querying the `pg_cursors` system view.

---

### Examples

Close the cursor *portala*:

```
CLOSE portala;
```

---

### Compatibility

`CLOSE` is fully conforming with the SQL standard.

---

### See Also

[DECLARE](#), [FETCH](#), [MOVE](#)

---

## CLUSTER

Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

---

### Synopsis

```
CLUSTER indexname ON tablename
```

```
CLUSTER tablename
```

```
CLUSTER
```

---

### Description

CLUSTER orders a heap storage table based on an index. CLUSTER is not supported on append-optimized storage tables. Clustering an index means that the records are physically ordered on disk according to the index information. If the records you need are distributed randomly on disk, then the database has to seek across the disk to get the records requested. If those records are stored more closely together, then the fetching from disk is more sequential. A good example for a clustered index is on a date column where the data is ordered sequentially by date. A query against a specific date range will result in an ordered fetch from the disk, which leverages faster sequential access.

Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. If one wishes, one can periodically recluster by issuing the command again.

When a table is clustered using this command, Greenplum Database remembers on which index it was clustered. The form `CLUSTER tablename` reclusters the table on the same index that it was clustered before. CLUSTER without any parameter reclusters all previously clustered tables in the current database that the calling user owns, or all tables if called by a superuser. This form of CLUSTER cannot be executed inside a transaction block.

When a table is being clustered, an `ACCESS EXCLUSIVE` lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the CLUSTER is finished.

---

### Parameters

***indexname***

The name of an index.

***tablename***

The name (optionally schema-qualified) of a table.

---

## Notes

In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index that groups them together, you will benefit from using `CLUSTER`. If you are requesting a range of indexed values from a table, or a single indexed value that has multiple rows that match, `CLUSTER` will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.

During the cluster operation, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

Because the query planner records statistics about the ordering of tables, it is advisable to run `ANALYZE` on the newly clustered table. Otherwise, the planner may make poor choices of query plans.

There is another way to cluster data. The `CLUSTER` command reorders the original table by scanning it using the index you specify. This can be slow on large tables because the rows are fetched from the table in index order, and if the table is disordered, the entries are on random pages, so there is one disk page retrieved for every row moved. (Greenplum Database has a cache, but the majority of a big table will not fit in the cache.) The other way to cluster a table is to use a statement such as:

```
CREATE TABLE newtable AS SELECT * FROM table ORDER BY column;
```

This uses the Greenplum Database sorting code to produce the desired order, which is usually much faster than an index scan for disordered data. Then you drop the old table, use `ALTER TABLE ... RENAME` to rename *newtable* to the old name, and recreate the table's indexes. The big disadvantage of this approach is that it does not preserve OIDs, constraints, granted privileges, and other ancillary properties of the table — all such items must be manually recreated. Another disadvantage is that this way requires a sort temporary file about the same size as the table itself, so peak disk usage is about three times the table size instead of twice the table size.

`CLUSTER` is not supported with append-optimized tables.

---

## Examples

Cluster the table *employees* on the basis of its index *emp\_ind*:

```
CLUSTER emp_ind ON emp;
```

Cluster a large table by recreating it and loading it in the correct index order:

```
CREATE TABLE newtable AS SELECT * FROM table ORDER BY column;
DROP table;
ALTER TABLE newtable RENAME TO table;
CREATE INDEX column_ix ON table (column);
VACUUM ANALYZE table;
```

---

**Compatibility**

There is no `CLUSTER` statement in the SQL standard.

---

**See Also**

`CREATE TABLE AS`, `CREATE INDEX`

---

## COMMENT

Defines or change the comment of an object.

---

### Synopsis

```
COMMENT ON
{ TABLE object_name |
  COLUMN table_name.column_name |
  AGGREGATE agg_name (agg_type [, ...]) |
  CAST (sourcetype AS targettype) |
  CONSTRAINT constraint_name ON table_name |
  CONVERSION object_name |
  DATABASE object_name |
  DOMAIN object_name |
  FILESPACE object_name |
  FUNCTION func_name ([[argmode] [argname] argtype [, ...]]) |
  INDEX object_name |
  LARGE OBJECT large_object_oid |
  OPERATOR op (leftoperand_type, rightoperand_type) |
  OPERATOR CLASS object_name USING index_method |
  [PROCEDURAL] LANGUAGE object_name |
  RESOURCE QUEUE object_name |
  ROLE object_name |
  RULE rule_name ON table_name |
  SCHEMA object_name |
  SEQUENCE object_name |
  TABLESPACE object_name |
  TRIGGER trigger_name ON table_name |
  TYPE object_name |
  VIEW object_name }
IS 'text'
```

---

### Description

COMMENT stores a comment about a database object. To modify a comment, issue a new COMMENT command for the same object. Only one comment string is stored for each object. To remove a comment, write NULL in place of the text string. Comments are automatically dropped when the object is dropped.

Comments can be easily retrieved with the psql meta-commands \dd, \d+, and \l+. Other user interfaces to retrieve comments can be built atop the same built-in functions that psql uses, namely obj\_description, col\_description, and shobj\_description.

---

### Parameters

*object\_name*  
*table\_name.column\_name*

*agg\_name*  
*constraint\_name*  
*func\_name*  
*op*  
*rule\_name*  
*trigger\_name*

The name of the object to be commented. Names of tables, aggregates, domains, functions, indexes, operators, operator classes, sequences, types, and views may be schema-qualified.

*agg\_type*

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write \* in place of the list of input data types.

*sourcetype*

The name of the source data type of the cast.

*targettype*

The name of the target data type of the cast.

*argmode*

The mode of a function argument: either IN, OUT, or INOUT. If omitted, the default is IN. Note that COMMENT ON FUNCTION does not actually pay any attention to OUT arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the IN and INOUT arguments.

*argname*

The name of a function argument. Note that COMMENT ON FUNCTION does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

*argtype*

The data type(s) of the function's arguments (optionally schema-qualified), if any.

*large\_object\_oid*

The OID of the large object.

**PROCEDURAL**

This is a noise word.

*text*

The new comment, written as a string literal; or NULL to drop the comment.

---

## Notes

There is presently no security mechanism for comments: any user connected to a database can see all the comments for objects in that database (although only superusers can change comments for objects that they do not own). For shared objects

such as databases, roles, and tablespaces comments are stored globally and any user connected to any database can see all the comments for shared objects. Therefore, do not put security-critical information in comments.

---

## Examples

Attach a comment to the table *mytable*:

```
COMMENT ON TABLE mytable IS 'This is my table.';
```

Remove it again:

```
COMMENT ON TABLE mytable IS NULL;
```

---

## Compatibility

There is no `COMMENT` statement in the SQL standard.

---

# COMMIT

Commits the current transaction.

---

## Synopsis

`COMMIT [WORK | TRANSACTION]`

---

## Description

`COMMIT` commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

---

## Parameters

`WORK`  
`TRANSACTION`

Optional key words. They have no effect.

---

## Notes

Use [ROLLBACK](#) to abort a transaction.

Issuing `COMMIT` when not inside a transaction does no harm, but it will provoke a warning message.

---

## Examples

To commit the current transaction and make all changes permanent:

```
COMMIT;
```

---

## Compatibility

The SQL standard only specifies the two forms `COMMIT` and `COMMIT WORK`. Otherwise, this command is fully conforming.

---

## See Also

[BEGIN](#), [END](#), [START TRANSACTION](#), [ROLLBACK](#)

## COPY

Copies data between a file and a table.

---

### Synopsis

```
COPY table [(column [, ...])] FROM {'file' | STDIN}
    [ [WITH]
      [OIDS]
      [HEADER]
      [DELIMITER [ AS ] 'delimiter']
      [NULL [ AS ] 'null string']
      [ESCAPE [ AS ] 'escape' | 'OFF']
      [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
      [CSV [QUOTE [ AS ] 'quote']
        [FORCE NOT NULL column [, ...]]
      [FILL MISSING FIELDS]
    [ [LOG ERRORS INTO error_table] [KEEP]
      SEGMENT REJECT LIMIT count [ROWS | PERCENT] ]
COPY {table [(column [, ...])] | (query)} TO {'file' | STDOUT}
    [ [WITH]
      [OIDS]
      [HEADER]
      [DELIMITER [ AS ] 'delimiter']
      [NULL [ AS ] 'null string']
      [ESCAPE [ AS ] 'escape' | 'OFF']
      [CSV [QUOTE [ AS ] 'quote']
        [FORCE QUOTE column [, ...]] ]
```

---

### Description

`COPY` moves data between Greenplum Database tables and standard file-system files. `COPY TO` copies the contents of a table to a file, while `COPY FROM` copies data from a file to a table (appending the data to whatever is in the table already). `COPY TO` can also copy the results of a `SELECT` query.

If a list of columns is specified, `COPY` will only copy the data in the specified columns to or from the file. If there are any columns in the table that are not in the column list, `COPY FROM` will insert the default values for those columns.

`COPY` with a file name instructs the Greenplum Database master host to directly read from or write to a file. The file must be accessible to the master host and the name must be specified from the viewpoint of the master host. When `STDIN` or `STDOUT` is specified, data is transmitted via the connection between the client and the master.

If `SEGMENT REJECT LIMIT` is used, then a `COPY FROM` operation will operate in single row error isolation mode. In this release, single row error isolation mode only applies to rows in the input file with format errors — for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in

‘all-or-nothing’ input mode. The user can specify the number of error rows acceptable (on a per-segment basis), after which the entire `COPY FROM` operation will be aborted and no rows will be loaded. Note that the count of error rows is per-segment, not per entire load operation. If the per-segment reject limit is not reached, then all rows not containing an error will be loaded. If the limit is not reached, all good rows will be loaded and any error rows discarded. If you would like to keep error rows for further examination, you can optionally declare an error table using the `LOG ERRORS INTO` clause. Any rows containing a format error would then be logged to the specified error table.

### Outputs

On successful completion, a `COPY` command returns a command tag of the form, where *count* is the number of rows copied:

```
COPY count
```

If running a `COPY FROM` command in single row error isolation mode, the following notice message will be returned if any rows were not loaded due to format errors, where *count* is the number of rows rejected:

```
NOTICE: Rejected count badly formatted rows.
```

---

### Parameters

#### ***table***

The name (optionally schema-qualified) of an existing table.

#### ***column***

An optional list of columns to be copied. If no column list is specified, all columns of the table will be copied.

#### ***query***

A `SELECT` or `VALUES` command whose results are to be copied. Note that parentheses are required around the query.

#### ***file***

The absolute path name of the input or output file.

#### **STDIN**

Specifies that input comes from the client application.

#### **STDOUT**

Specifies that output goes to the client application.

#### **OIDS**

Specifies copying the OID for each row. (An error is raised if `OIDS` is specified for a table that does not have OIDs, or in the case of copying a query.)

***delimiter***

The single ASCII character that separates columns within each row (line) of the file. The default is a tab character in text mode, a comma in CSV mode.

***null string***

The string that represents a null value. The default is \N (backslash-N) in text mode, and an empty value with no quotes in CSV mode. You might prefer an empty string even in text mode for cases where you don't want to distinguish nulls from empty strings. When using `COPY FROM`, any data item that matches this string will be stored as a null value, so you should make sure that you use the same string as you used with `COPY TO`.

***escape***

Specifies the single character that is used for C escape sequences (such as \n, \t, \100, and so on) and for quoting data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is \ (backslash) for text files or " (double quote) for CSV files, however it is possible to specify any other character to represent an escape. It is also possible to disable escaping on text-formatted files by specifying the value 'OFF' as the escape value. This is very useful for data such as web log data that has many embedded backslashes that are not intended to be escapes.

**NEWLINE**

Specifies the newline used in your data files — LF (Line feed, 0x0A), CR (Carriage return, 0x0D), or CRLF (Carriage return plus line feed, 0x0D 0x0A). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

**CSV**

Selects Comma Separated Value (CSV) mode.

**HEADER**

Specifies that a file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table, and on input, the first line is ignored.

***quote***

Specifies the quotation character in CSV mode. The default is double-quote.

**FORCE QUOTE**

In CSV `COPY TO` mode, forces quoting to be used for all non-NULL values in each specified column. NULL output is never quoted.

**FORCE NOT NULL**

In `CSV COPY FROM` mode, process each specified column as though it were quoted and hence not a `NULL` value. For the default null string in `CSV` mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

**FILL MISSING FIELDS**

In `COPY FROM` mode for both `TEXT` and `CSV`, specifying `FILL MISSING FIELDS` will set missing trailing field values to `NULL` (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

**LOG ERRORS INTO *error\_table* [KEEP]**

This is an optional clause that may precede a `SEGMENT REJECT LIMIT` clause. It specifies an error table where rows with formatting errors will be logged when running in single row error isolation mode. You can then examine this error table to see error rows that were not loaded (if any). If the *error\_table* specified already exists, it will be used. If it does not exist, it will be automatically generated. If the command auto-generates the error table and no errors are produced, the default is to drop the error table after the operation completes unless `KEEP` is specified. If the table is auto-generated and the error limit is exceeded, the entire transaction is rolled back and no error data is saved. If you want the error table to persist in this case, create the error table prior to running the `COPY`. An error table is defined as follows:

```
CREATE TABLE error_table_name ( cmdtime timestampz,
    relname text, filename text, linenum int, bytenum int,
    errmsg text, rawdata text, rawbytes bytea )
DISTRIBUTED RANDOMLY;
```

**SEGMENT REJECT LIMIT *count* [ROWS | PERCENT]**

Runs a `COPY FROM` operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If `PERCENT` is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter `gp_reject_percent_threshold` has been processed. The default for `gp_reject_percent_threshold` is 300 rows. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in ‘all-or-nothing’ input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

---

**Notes**

`COPY` can only be used with tables, not with views. However, you can write `COPY (SELECT * FROM viewname) TO ....`

The `BINARY` key word causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the normal text mode, but a binary-format file is less portable across machine architectures and Greenplum Database versions. Also, you cannot run `COPY FROM` in single row error isolation mode if the data is in binary format.

You must have `SELECT` privilege on the table whose values are read by `COPY TO`, and insert privilege on the table into which values are inserted by `COPY FROM`.

Files named in a `COPY` command are read or written directly by the database server, not by the client application. Therefore, they must reside on or be accessible to the Greenplum Database master host machine, not the client. They must be accessible to and readable or writable by the Greenplum Database system user (the user ID the server runs as), not the client. `COPY` naming a file is only allowed to database superusers, since it allows reading or writing any file that the server has privileges to access.

`COPY FROM` will invoke any triggers and check constraints on the destination table. However, it will not invoke rewrite rules. Note that in this release, violations of constraints are not evaluated for single row error isolation mode.

`COPY` input and output is affected by `DateStyle`. To ensure portability to other Greenplum Database installations that might use non-default `DateStyle` settings, `DateStyle` should be set to `ISO` before using `COPY TO`.

By default, `COPY` stops operation at the first error. This should not lead to problems in the event of a `COPY TO`, but the target table will already have received earlier rows in a `COPY FROM`. These rows will not be visible or accessible, but they still occupy disk space. This may amount to a considerable amount of wasted disk space if the failure happened well into a large `COPY FROM` operation. You may wish to invoke `VACUUM` to recover the wasted space. Another option would be to use single row error isolation mode to filter out error rows while still loading good rows.

---

## File Formats

### Text Format

When `COPY` is used without the `BINARY` or `CSV` options, the data read or written is a text file with one line per table row. Columns in a row are separated by the *delimiter* character (tab by default). The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. `COPY FROM` will raise an error if any line of the input file contains more or fewer columns than are expected. If `OIDS` is specified, the OID is read or written as the first column, preceding the user data columns.

The data file has two reserved characters that have special meaning to `COPY`:

- The designated delimiter character (tab by default), which is used to separate fields in the data file.

- A UNIX-style line feed (`\n` or `0x0a`), which is used to designate a new row in the data file. It is strongly recommended that applications generating `COPY` data convert data line feeds to UNIX-style line feeds rather than Microsoft Windows style carriage return line feeds (`\r\n` or `0x0a 0x0d`).

If your data contains either of these characters, you must escape the character so `COPY` treats it as data and not as a field separator or new row.

By default, the escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files. If you want to use a different escape character, you can do so using the `ESCAPE AS` clause. Make sure to choose an escape character that is not used anywhere in your data file as an actual data value. You can also disable escaping in text-formatted files by using `ESCAPE 'OFF'`.

For example, suppose you have a table with three columns and you want to load the following three fields using `COPY`.

- percentage sign = %
- vertical bar = |
- backslash = \

Your designated `DELIMITER` character is `|` (pipe character), and your designated `ESCAPE` character is `*` (asterisk). The formatted row in your data file would look like this:

```
percentage sign = % | vertical bar = * | | backslash = \
```

Notice how the pipe character that is part of the data has been escaped using the asterisk character (`*`). Also notice that we do not need to escape the backslash since we are using an alternative escape character.

The following characters must be preceded by the escape character if they appear as part of a column value: the escape character itself, newline, carriage return, and the current delimiter character. You can specify a different escape character using the `ESCAPE AS` clause.

### CSV Format

This format is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping used by Greenplum Database standard text mode, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the `DELIMITER` character. If the value contains the delimiter character, the `QUOTE` character, the `ESCAPE` character (which is double quote by default), the `NULL` string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the `QUOTE` character. You can also use `FORCE QUOTE` to force quotes when outputting non-`NULL` values in specific columns.

The CSV format has no standard way to distinguish a `NULL` value from an empty string. Greenplum Database `COPY` handles this by quoting. A `NULL` is output as the `NULL` string and is not quoted, while a data value matching the `NULL` string is quoted. Therefore, using the default settings, a `NULL` is written as an unquoted empty string,

while an empty string is written with double quotes ("" ). Reading values follows similar rules. You can use `FORCE NOT NULL` to prevent `NULL` input comparisons for specific columns.

Because backslash is not a special character in the CSV format, `\.`, the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a `\.` data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of `\.`, you might need to quote that value in the input file.

**Note:** In CSV mode, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, will include those characters. This can cause errors if you import data from a system that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into Greenplum Database.

**Note:** CSV mode will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. Thus the files are not strictly one line per table row like text-mode files.

**Note:** Many programs produce strange and occasionally perverse CSV files, so the file format is more a convention than a standard. Thus you might encounter some files that cannot be imported using this mechanism, and `COPY` might produce files that other programs cannot process.

## Binary Format

The `BINARY` format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are in network byte order.

- **File Header** — The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:
  - **Signature** — 11-byte sequence `PGCOPY\0377\0` — note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)
  - **Flags field** — 32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16-31 are reserved to denote critical file format issues; a reader should abort if it finds an unexpected bit set in this range. Bits 0-15 are reserved to signal backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag is defined, and the rest must be zero (Bit 16: 1 if data has OIDs, 0 if not).
  - **Header extension area length** — 32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be present in the header. A reader should silently skip over any header extension

data it does not know what to do with. The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area. Specific design of header extension contents is left for a later release.

- **Tuples** — Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (Presently, all tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.

Presently, all data values in a COPY BINARY file are assumed to be in binary format (format code one). It is anticipated that a future extension may add a header field that allows per-column format codes to be specified.

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it's not included in the field-count. In particular it has a length word — this will allow handling of 4-byte vs. 8-byte OIDs without too much pain, and will allow OIDs to be shown as null if that ever proves desirable.

- **File Trailer** — The file trailer consists of a 16-bit integer word containing -1. This is easily distinguished from a tuple's field-count word. A reader should report an error if a field-count word is neither -1 nor the expected number of columns. This provides an extra check against somehow getting out of sync with the data.

---

## Examples

Copy a table to the client using the vertical bar (|) as the field delimiter:

```
COPY country TO STDOUT WITH DELIMITER '|';
```

Copy data from a file into the *country* table:

```
COPY country FROM '/home/usr1/sql/country_data';
```

Copy into a file just the countries whose names start with 'A':

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO
'/home/usr1/sql/a_list_countries.copy';
```

Create an error table called *err\_sales* to use with single row error isolation mode:

```
CREATE TABLE err_sales ( cmdtime timestamptz, relname
text, filename text, linenum int, bytenum int, errmsg
text, rawdata text, rawbytes bytea )
DISTRIBUTED RANDOMLY;
```

Copy data from a file into the *sales* table using single row error isolation mode:

```
COPY sales FROM '/home/usr1/sql/sales_data' LOG ERRORS INTO
err_sales SEGMENT REJECT LIMIT 10 ROWS;
```

---

## Compatibility

There is no COPY statement in the SQL standard.

## CREATE AGGREGATE

Defines a new aggregate function.

---

### Synopsis

```
CREATE [ORDERED] AGGREGATE name (input_data_type [ , ... ])
    ( SFUNC = sfunc,
      STYPE = state_data_type
      [, PREFUNC = prefunc]
      [, FINALFUNC = ffunc]
      [, INITCOND = initial_condition]
      [, SORTOP = sort_operator] )
```

---

### Description

`CREATE AGGREGATE` defines a new aggregate function. Some basic and commonly-used aggregate functions such as `count`, `min`, `max`, `sum`, `avg` and so on are already provided in Greenplum Database. If one defines new types or needs an aggregate function not already provided, then `CREATE AGGREGATE` can be used to provide the desired features.

An aggregate function is identified by its name and input data type(s). Two aggregates in the same schema can have the same name if they operate on different input types. The name and input data type(s) of an aggregate must also be distinct from the name and input data type(s) of every ordinary function in the same schema.

An aggregate function is made from one, two or three ordinary functions (all of which must be `IMMUTABLE` functions): a state transition function *sfunc*, an optional preliminary segment-level calculation function *prefunc*, and an optional final calculation function *ffunc*. These are used as follows:

```
sfunc( internal-state, next-data-values ) ---> next-internal-state
prefunc( internal-state, internal-state ) ---> next-internal-state
ffunc( internal-state ) ---> aggregate-value
```

Greenplum Database creates a temporary variable of data type *stype* to hold the current internal state of the aggregate. At each input row, the aggregate argument value(s) are calculated and the state transition function is invoked with the current state value and the new argument value(s) to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate's return value. If there is no final function then the ending state value is returned as-is.

An aggregate function may provide an initial condition, that is, an initial value for the internal state value. This is specified and stored in the database as a value of type `text`, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out null.

If the state transition function is declared strict, then it cannot be called with null inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state

value is retained). If the initial state value is null, then at the first row with all-nonnull input values, the first argument value replaces the state value, and the transition function is invoked at subsequent rows with all-nonnull input values. This is handy for implementing aggregates like `max`. Note that this behavior is only available when `state_data_type` is the same as the first `input_data_type`. When these types are different, you must supply a nonnull initial condition or use a nonstrict transition function.

If the state transition function is not strict, then it will be called unconditionally at each input row, and must deal with null inputs and null transition values for itself. This allows the aggregate author to have full control over the aggregate's handling of null values.

If the final function is declared strict, then it will not be called when the ending state value is null; instead a null result will be returned automatically. (Of course this is just the normal behavior of strict functions.) In any case the final function has the option of returning a null value. For example, the final function for `avg` returns null when it sees there were zero input rows.

Single argument aggregate functions, such as `min` or `max`, can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a sort operator. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words

```
SELECT agg(col) FROM tab;
```

must be equivalent to:

```
SELECT col FROM tab ORDER BY col USING sortop LIMIT 1;
```

Further assumptions are that the aggregate ignores null inputs, and that it delivers a null result if and only if there were no non-null inputs. Ordinarily, a data type's `<` operator is the proper sort operator for `MIN`, and `>` is the proper sort operator for `MAX`. Note that the optimization will never actually take effect unless the specified operator is the "less than" or "greater than" strategy member of a B-tree index operator class.

### Ordered Aggregates

If the optional qualification `ORDERED` appears, the created aggregate function is an *ordered aggregate*. In this case, the preliminary aggregation function, `prefunc` cannot be specified.

An ordered aggregate is called with the following syntax.

```
name ( arg [ , ... ] [ORDER BY sortspec [ , ...]] )
```

If the optional `ORDER BY` is omitted, a system-defined ordering is used. The transition function of an ordered aggregate `sfunc` is called on its input arguments in the specified order and on a single segment. There is a new column `aggordered` in the `pg_aggregate` table to indicate the aggregate function is defined as an ordered aggregate.

---

## Parameters

***name***

The name (optionally schema-qualified) of the aggregate function to create.

***input\_data\_type***

An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write *\** in place of the list of input data types. An example of such an aggregate is `count(*)`.

***sfunc***

The name of the state transition function to be called for each input row. For an N-argument aggregate function, the *sfunc* must take N+1 arguments, the first being of type *state\_data\_type* and the rest matching the declared input data type(s) of the aggregate. The function must return a value of type *state\_data\_type*. This function takes the current state value and the current input data value(s), and returns the next state value.

***state\_data\_type***

The data type for the aggregate's state value.

***prefunc***

The name of a preliminary aggregation function. This is a function of two arguments, both of type *state\_data\_type*. It must return a value of *state\_data\_type*. A preliminary function takes two transition state values and returns a new transition state value representing the combined aggregation. In Greenplum Database, if the result of the aggregate function is computed in a segmented fashion, the preliminary aggregation function is invoked on the individual internal states in order to combine them into an ending internal state.

Note that this function is also called in hash aggregate mode within a segment. Therefore if you call this aggregate function without a preliminary function, hash aggregate is never chosen. Since hash aggregate is efficient, consider defining preliminary function whenever possible.

***ffunc***

The name of the final function called to compute the aggregate's result after all input rows have been traversed. The function must take a single argument of type *state\_data\_type*. The return data type of the aggregate is defined as the return type of this function. If *ffunc* is not specified, then the ending state value is used as the aggregate's result, and the return type is *state\_data\_type*.

***initial\_condition***

The initial setting for the state value. This must be a string constant in the form accepted for the data type *state\_data\_type*. If not specified, the state value starts out null.

***sort\_operator***

The associated sort operator for a MIN- or MAX-like aggregate. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate (which must be a single-argument aggregate).

---

**Notes**

The ordinary functions used to define a new aggregate function must be defined first. Note that in this release of Greenplum Database, it is required that the *sfunc*, *ffunc*, and *prefunc* functions used to create the aggregate are defined as IMMUTABLE.

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the LD\_LIBRARY\_PATH so that the server can locate the files.

---

**Examples**

Create a sum of cubes aggregate:

```
CREATE FUNCTION scube_accum(numeric, numeric) RETURNS
numeric
AS 'select $1 + $2 * $2 * $2'
LANGUAGE SQL
IMMUTABLE
RETURNS NULL ON NULL INPUT;
CREATE AGGREGATE scube(numeric) (
  SFUNC = scube_accum,
  STYPE = numeric,
  INITCOND = 0 );
```

To test this aggregate:

```
CREATE TABLE x(a INT);
INSERT INTO x VALUES (1), (2), (3);
SELECT scube(a) FROM x;
```

Correct answer for reference:

```
SELECT sum(a*a*a) FROM x;
```

---

**Compatibility**

CREATE AGGREGATE is a Greenplum Database language extension. The SQL standard does not provide for user-defined aggregate functions.

---

**See Also**

[ALTER AGGREGATE](#), [DROP AGGREGATE](#), [CREATE FUNCTION](#)

## CREATE CAST

Defines a new cast.

### Synopsis

```
CREATE CAST (sourcetype AS targettype)
    WITH FUNCTION funcname (argtypes)
    [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (sourcetype AS targettype) WITHOUT FUNCTION
    [AS ASSIGNMENT | AS IMPLICIT]
```

### Description

CREATE CAST defines a new cast. A cast specifies how to perform a conversion between two data types. For example,

```
SELECT CAST(42 AS text);
```

converts the integer constant *42* to type *text* by invoking a previously specified function, in this case *text(int4)*. If no suitable cast has been defined, the conversion fails.

Two types may be binary compatible, which means that they can be converted into one another without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types *text* and *varchar* are binary compatible.

By default, a cast can be invoked only by an explicit cast request, that is an explicit *CAST(x AS typename)* or *x::typename* construct.

If the cast is marked *AS ASSIGNMENT* then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that *foo.f1* is a column of type *text*, then

```
INSERT INTO foo (f1) VALUES (42);
```

will be allowed if the cast from type *integer* to type *text* is marked *AS ASSIGNMENT*, otherwise not. The term *assignment cast* is typically used to describe this kind of cast.

If the cast is marked *AS IMPLICIT* then it can be invoked implicitly in any context, whether assignment or internally in an expression. The term *implicit cast* is typically used to describe this kind of cast. For example, since *||* takes *text* operands,

```
SELECT 'The time is ' || now();
```

will be allowed only if the cast from type *timestamp* to *text* is marked *AS IMPLICIT*. Otherwise, it will be necessary to write the cast explicitly, for example

```
SELECT 'The time is ' || CAST(now() AS text);
```

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause Greenplum Database to choose surprising interpretations of commands, or to be unable to resolve commands at all because there

are multiple possible interpretations. A good rule of thumb is to make a cast implicitly invocable only for information-preserving transformations between types in the same general type category. For example, the cast from `int2` to `int4` can reasonably be implicit, but the cast from `float8` to `int4` should probably be assignment-only. Cross-type-category casts, such as `text` to `int4`, are best made explicit-only.

To be able to create a cast, you must own the source or the target data type. To create a binary-compatible cast, you must be superuser.

---

## Parameters

### *sourcetype*

The name of the source data type of the cast.

### *targettype*

The name of the target data type of the cast.

### *funcname(argtypes)*

The function used to perform the cast. The function name may be schema-qualified. If it is not, the function will be looked up in the schema search path. The function's result data type must match the target type of the cast.

Cast implementation functions may have one to three arguments. The first argument type must be identical to the cast's source type. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise. The SQL specification demands different behaviors for explicit and implicit casts in some cases. This argument is supplied for functions that must implement such casts. It is not recommended that you design your own data types this way.

Ordinarily a cast must have different source and target data types. However, it is allowed to declare a cast with identical source and target types if it has a cast implementation function with more than one argument. This is used to represent type-specific length coercion functions in the system catalogs. The named function is used to coerce a value of the type to the type modifier value given by its second argument. (Since the grammar presently permits only certain built-in data types to have type modifiers, this feature is of no use for user-defined target types.)

When a cast has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

### **WITHOUT FUNCTION**

Indicates that the source type and the target type are binary compatible, so no function is required to perform the cast.

**AS ASSIGNMENT**

Indicates that the cast may be invoked implicitly in assignment contexts.

**AS IMPLICIT**

Indicates that the cast may be invoked implicitly in any context.

---

**Notes**

Note that in this release of Greenplum Database, user-defined functions used in a user-defined cast must be defined as `IMMUTABLE`. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

Remember that if you want to be able to convert types both ways you need to declare casts both ways explicitly.

It is recommended that you follow the convention of naming cast implementation functions after the target data type, as the built-in cast implementation functions are named. Many users are used to being able to cast data types using a function-style notation, that is *typename(x)*.

---

**Examples**

To create a cast from type *text* to type *int4* using the function *int4(text)* (This cast is already predefined in the system.):

```
CREATE CAST (text AS int4) WITH FUNCTION int4(text);
```

---

**Compatibility**

The `CREATE CAST` command conforms to the SQL standard, except that SQL does not make provisions for binary-compatible types or extra arguments to implementation functions. `AS IMPLICIT` is a Greenplum Database extension, too.

---

**See Also**

[CREATE FUNCTION](#), [CREATE TYPE](#), [DROP CAST](#)

---

## CREATE CONVERSION

Defines a new encoding conversion.

---

### Synopsis

```
CREATE [DEFAULT] CONVERSION name FOR source_encoding TO
dest_encoding FROM funcname
```

---

### Description

CREATE CONVERSION defines a new conversion between character set encodings. Conversion names may be used in the convert function to specify a particular encoding conversion. Also, conversions that are marked DEFAULT can be used for automatic encoding conversion between client and server. For this purpose, two conversions, from encoding A to B and from encoding B to A, must be defined.

To create a conversion, you must have EXECUTE privilege on the function and CREATE privilege on the destination schema.

---

### Parameters

#### DEFAULT

Indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

#### *name*

The name of the conversion. The conversion name may be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

#### *source\_encoding*

The source encoding name.

#### *dest\_encoding*

The destination encoding name.

#### *funcname*

The function used to perform the conversion. The function name may be schema-qualified. If it is not, the function will be looked up in the path. The function must have the following signature:

```
conv_proc (
    integer, -- source encoding ID
    integer, -- destination encoding ID
    cstring, -- source string (null terminated C string)
    internal, -- destination (fill with a null terminated C string)
    integer -- source string length
```

```
) RETURNS void;
```

---

## Notes

Note that in this release of Greenplum Database, user-defined functions used in a user-defined conversion must be defined as `IMMUTABLE`. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

---

## Examples

To create a conversion from encoding *UTF8* to *LATIN1* using *myfunc*:

```
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

---

## Compatibility

There is no `CREATE CONVERSION` statement in the SQL standard.

---

## See Also

[ALTER CONVERSION](#), [CREATE FUNCTION](#), [DROP CONVERSION](#)

---

## CREATE DATABASE

Creates a new database.

---

### Synopsis

```
CREATE DATABASE name [ [WITH] [OWNER [=] dbowner]
                    [TEMPLATE [=] template]
                    [ENCODING [=] encoding]
                    [TABLESPACE [=] tablespace]
                    [CONNECTION LIMIT [=] connlimit ] ]
```

---

### Description

`CREATE DATABASE` creates a new database. To create a database, you must be a superuser or have the special `CREATEDB` privilege.

The creator becomes the owner of the new database by default. Superusers can create databases owned by other users by using the `OWNER` clause. They can even create databases owned by users with no special privileges. Non-superusers with `CREATEDB` privilege can only create databases owned by themselves.

By default, the new database will be created by cloning the standard system database *template1*. A different template can be specified by writing `TEMPLATE name`. In particular, by writing `TEMPLATE template0`, you can create a clean database containing only the standard objects predefined by Greenplum Database. This is useful if you wish to avoid copying any installation-local objects that may have been added to *template1*.

---

### Parameters

#### *name*

The name of a database to create.

#### *dbowner*

The name of the database user who will own the new database, or `DEFAULT` to use the default owner (the user executing the command).

#### *template*

The name of the template from which to create the new database, or `DEFAULT` to use the default template (*template1*).

#### *encoding*

Character set encoding to use in the new database. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or `DEFAULT` to use the default encoding. See [“Character Set Support”](#) on page 471.

***tablespace***

The name of the tablespace that will be associated with the new database, or `DEFAULT` to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database.

***connlimit***

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

---

**Notes**

`CREATE DATABASE` cannot be executed inside a transaction block.

When you copy a database by specifying its name as the template, no other sessions can be connected to the template database while it is being copied. New connections to the template database are locked out until `CREATE DATABASE` completes.

The `CONNECTION LIMIT` is not enforced against superusers.

---

**Examples**

To create a new database:

```
CREATE DATABASE gpdb;
```

To create a database *sales* owned by user *salesapp* with a default tablespace of *salesspace*:

```
CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;
```

To create a database *music* which supports the ISO-8859-1 character set:

```
CREATE DATABASE music ENCODING 'LATIN1';
```

---

**Compatibility**

There is no `CREATE DATABASE` statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

---

**See Also**

[ALTER DATABASE](#), [DROP DATABASE](#)

---

## CREATE DOMAIN

Defines a new domain.

---

### Synopsis

```
CREATE DOMAIN name [AS] data_type [DEFAULT expression]
    [CONSTRAINT constraint_name
    | NOT NULL | NULL
    | CHECK (expression) [...]]
```

---

### Description

`CREATE DOMAIN` creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner. The domain name must be unique among the data types and domains existing in its schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same `CHECK` constraint to verify the address syntax. It is easier to define a domain rather than setting up a column constraint for each table that has an email column.

---

### Parameters

#### ***name***

The name (optionally schema-qualified) of a domain to be created.

#### ***data\_type***

The underlying data type of the domain. This may include array specifiers.

#### **DEFAULT *expression***

Specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression must match the data type of the domain. If no default value is specified, then the default value is the null value. The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

#### **CONSTRAINT *constraint\_name***

An optional name for a constraint. If not specified, the system generates a name.

#### **NOT NULL**

Values of this domain are not allowed to be null.

**NULL**

Values of this domain are allowed to be null. This is the default. This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

**CHECK (*expression*)**

CHECK clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word `VALUE` to refer to the value being tested. Currently, CHECK expressions cannot contain subqueries nor refer to variables other than `VALUE`.

---

**Examples**

Create the *us\_zip\_code* data type. A regular expression test is used to verify that the value looks like a valid US zip code.

```
CREATE DOMAIN us_zip_code AS TEXT CHECK
( VALUE ~ '^\\d{5}$' OR VALUE ~ '^\\d{5}-\\d{4}$' );
```

---

**Compatibility**

CREATE DOMAIN conforms to the SQL standard.

---

**See Also**

[ALTER DOMAIN](#), [DROP DOMAIN](#)

## CREATE EXTERNAL TABLE

Defines a new external table.

### Synopsis

```
CREATE [READABLE] EXTERNAL TABLE table_name
  ( column_name data_type [, ...] | LIKE other_table )
  LOCATION ('file://seghost[:port]/path/file' [, ...])
    | ('gpfdist://filehost[:port]/file_pattern[#transform]'

[ ENCODING 'write_encoding' ]
[ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]

```

---

## Description

See the *Greenplum Database Database Administrator Guide* for detailed information about external tables.

`CREATE EXTERNAL TABLE` or `CREATE EXTERNAL WEB TABLE` creates a new readable external table definition in Greenplum Database. Readable external tables are typically used for fast, parallel data loading. Once an external table is defined, you can query its data directly (and in parallel) using SQL commands. For example, you can select, join, or sort external table data. You can also create views for external tables. DML operations (`UPDATE`, `INSERT`, `DELETE`, or `TRUNCATE`) are not allowed on readable external tables, and you cannot create indexes on readable external tables.

`CREATE WRITABLE EXTERNAL TABLE` or `CREATE WRITABLE EXTERNAL WEB TABLE` creates a new writable external table definition in Greenplum Database. Writable external tables are typically used for unloading data from the database into a set of files or named pipes. Writable external web tables can also be used to output data to an executable program. Writable external tables can also be used as output targets for Greenplum parallel MapReduce calculations. Once a writable external table is defined, data can be selected from database tables and inserted into the writable external table. Writable external tables only allow `INSERT` operations – `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` are not allowed.

The main difference between regular external tables and web external tables is their data sources. Regular readable external tables access static flat files, whereas web external tables access dynamic data sources – either on a web server or by executing OS commands or scripts.

The `FORMAT` clause is used to describe how the external table files are formatted. Valid file formats are delimited text (`TEXT`) for all protocols and comma separated values (CSV) format for `gpfdist` and `file` protocols, similar to the formatting options available with the PostgreSQL `COPY` command. If the data in the file does not use the default column delimiter, escape character, null string and so on, you must specify the additional formatting options so that the data in the external file is read correctly by Greenplum Database. For information about using a custom format, see the *Greenplum Database Database Administrator Guide*.

---

## Parameters

### **READABLE | WRITABLE**

Specifies the type of external table, readable being the default. Readable external tables are used for loading data into Greenplum Database. Writable external tables are used for unloading data.

### **WEB**

Creates a readable or writable web external table definition in Greenplum Database. There are two forms of readable web external tables – those that access files via the `http://` protocol or those that access data by executing OS commands. Writable web external tables output data to an executable program that can accept an input stream of data. Web external tables are not rescannable during query execution.

***table\_name***

The name of the new external table.

***column\_name***

The name of a column to create in the external table definition. Unlike regular tables, external tables do not have column constraints or default values, so do not specify those.

***LIKE other\_table***

The **LIKE** clause specifies a table from which the new external table automatically copies all column names, data types and Greenplum distribution policy. If the original table specifies any column constraints or default column values, those will not be copied over to the new external table definition.

***data\_type***

The data type of the column.

***LOCATION ('protocol://host[:port]/path/file' [, ...])***

For readable external tables, specifies the URI of the external data source(s) to be used to populate the external table or web table. Regular readable external tables allow the `gpfdist` or `file` protocols. Web external tables allow the `http` protocol. If `port` is omitted, port 8080 is assumed for `http` and `gpfdist` protocols, and port 9000 for the `gphdfs` protocol. If using the `gpfdist` protocol, the path is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). Also, `gpfdist` can use wildcards (or other C-style pattern matching) to denote multiple files in a directory. For example:

```
'gpfdist://filehost:8081/*'
'gpfdist://masterhost/my_load_file'
'file://seghost1/dbfast1/external/myfile.txt'
'http://intranet.mycompany.com/finance/expenses.csv'
```

For writable external tables, specifies the URI location of the `gpfdist` process that will collect data output from the Greenplum segments and write it to the named file. The path is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). If multiple `gpfdist` locations are listed, the segments sending data will be evenly divided across the available output locations. For example:

```
'gpfdist://outpuhost:8081/data1.out',
'gpfdist://outpuhost:8081/data2.out'
```

With two `gpfdist` locations listed as in the above example, half of the segments would send their output data to the `data1.out` file and the other half to the `data2.out` file.

**EXECUTE 'command' [ON ...]**

Allowed for readable web external tables or writable external tables only. For readable web external tables, specifies the OS command to be executed by the segment instances. The *command* can be a single OS command or a script. The **ON** clause is used to specify which segment instances will execute the given command.

- **ON ALL** is the default. The command will be executed by every active (primary) segment instance on all segment hosts in the Greenplum Database system. If the command executes a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (gpadmin).
- **ON MASTER** runs the command on the master host only.
- **ON number** means the command will be executed by the specified number of segments. The particular segments are chosen randomly at runtime by the Greenplum Database system. If the command executes a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (gpadmin).
- **HOST** means the command will be executed by one segment on each segment host (once per segment host), regardless of the number of active segment instances per host.
- **HOST segment\_hostname** means the command will be executed by all active (primary) segment instances on the specified segment host.
- **SEGMENT segment\_id** means the command will be executed only once by the specified segment. You can determine a segment instance's ID by looking at the *content* number in the system catalog table *gp\_segment\_configuration*. The *content* ID of the Greenplum Database master is always -1.

For writable external tables, the *command* specified in the **EXECUTE** clause must be prepared to have data piped into it. Since all segments that have data to send will write their output to the specified command or program, the only available option for the **ON** clause is **ON ALL**.

**FORMAT 'TEXT' | 'CSV' (options)**

Specifies the format of the external or web table data - either plain text (TEXT) or comma separated values (CSV) format. CSV format is supported only for the gpfdist and file protocols.

**DELIMITER**

Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in TEXT mode, a comma in CSV mode. In TEXT mode for readable external tables, the delimiter can be set to OFF for special use cases in which unstructured data is loaded into a single-column table.

**NULL**

Specifies the string that represents a `NULL` value. The default is `\N` (backslash-N) in `TEXT` mode, and an empty value with no quotations in `CSV` mode. You might prefer an empty string even in `TEXT` mode for cases where you do not want to distinguish `NULL` values from empty strings. When using external and web tables, any data item that matches this string will be considered a `NULL` value.

As an example for the `text` format, this `FORMAT` clause can be used to specify that the string of two single quotes (`' '`) is a `NULL` value.

```
FORMAT 'text' (delimiter ',' null '\'\'' )
```

**ESCAPE**

Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping in text-formatted files by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

**NEWLINE**

Specifies the newline used in your data files – `LF` (Line feed, `0x0A`), `CR` (Carriage return, `0x0D`), or `CRLF` (Carriage return plus line feed, `0x0D 0x0A`). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

**HEADER**

For readable external tables, specifies that the first line in the data file(s) is a header row (contains the names of the table columns) and should not be included as data for the table. If using multiple data source files, all files must have a header row.

**QUOTE**

Specifies the quotation character for `CSV` mode. The default is double-quote (`"`).

**FORCE NOT NULL**

In `CSV` mode, processes each specified column as though it were quoted and hence not a `NULL` value. For the default null string in `CSV` mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

**FORCE QUOTE**

In `CSV` mode for writable external tables, forces quoting to be used for all non-`NULL` values in each specified column. `NULL` output is never quoted.

**FILL MISSING FIELDS**

In both `TEXT` and `CSV` mode for readable external tables, specifying `FILL MISSING FIELDS` will set missing trailing field values to `NULL` (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

**ENCODING 'encoding'**

Character set encoding to use for the external table. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or `DEFAULT` to use the default client encoding. See [“Character Set Support”](#) on page 471.

**LOG ERRORS INTO *error\_table***

This is an optional clause that may precede a `SEGMENT REJECT LIMIT` clause. It specifies an error table where rows with formatting errors will be logged when running in single row error isolation mode. You can then examine this error table to see error rows that were not loaded (if any). If the *error\_table* specified already exists, it will be used. If it does not exist, it will be automatically generated.

**SEGMENT REJECT LIMIT *count* [ROWS | PERCENT]**

Runs a `COPY FROM` operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If `PERCENT` is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter `gp_reject_percent_threshold` has been processed. The default for `gp_reject_percent_threshold` is 300 rows. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in “all-or-nothing” input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

**DISTRIBUTED BY (*column*, [ ... ] )  
DISTRIBUTED RANDOMLY**

Used to declare the Greenplum Database distribution policy for a writable external table. By default, writable external tables are distributed randomly. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) for the writable external table will improve unload performance by eliminating the need to move rows over the interconnect. When you issue an unload command such as `INSERT INTO wex_table SELECT * FROM source_table`, the rows that are unloaded can be sent directly from the segments to the output location if the two tables have the same hash distribution policy.

---

**Examples**

Start the `gpfdist` file server program in the background on port `8081` serving files from directory `/var/data/staging`:

```
gpfdist -p 8081 -d /var/data/staging -l /home/gpadmin/log &
```

Create a readable external table named *ext\_customer* using the *gpfdist* protocol and any text formatted files (\*.txt) found in the *gpfdist* directory. The files are formatted with a pipe (|) as the column delimiter and an empty space as NULL. Also access the external table in single row error isolation mode:

```
CREATE EXTERNAL TABLE ext_customer
  (id int, name text, sponsor text)
  LOCATION ( 'gpfdist://filehost:8081/*.txt' )
  FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
  LOG ERRORS INTO err_customer SEGMENT REJECT LIMIT 5;
```

Create the same readable external table definition as above, but with CSV formatted files:

```
CREATE EXTERNAL TABLE ext_customer
  (id int, name text, sponsor text)
  LOCATION ( 'gpfdist://filehost:8081/*.csv' )
  FORMAT 'CSV' ( DELIMITER ',' );
```

Create a readable external table named *ext\_expenses* using the *file* protocol and several CSV formatted files that have a header row:

```
CREATE EXTERNAL TABLE ext_expenses (name text, date date,
amount float4, category text, description text)
LOCATION (
'file://seghost1/dbfast/external/expenses1.csv',
'file://seghost1/dbfast/external/expenses2.csv',
'file://seghost2/dbfast/external/expenses3.csv',
'file://seghost2/dbfast/external/expenses4.csv',
'file://seghost3/dbfast/external/expenses5.csv',
'file://seghost3/dbfast/external/expenses6.csv'
)
FORMAT 'CSV' ( HEADER );
```

Create a readable web external table that executes a script once per segment host:

```
CREATE EXTERNAL WEB TABLE log_output (linenum int, message
text) EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
FORMAT 'TEXT' (DELIMITER '|');
```

Create a writable external table named *sales\_out* that uses *gpfdist* to write output data to a file named *sales.out*. The files are formatted with a pipe (|) as the column delimiter and an empty space as NULL.

```
CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
  LOCATION ('gpfdist://etl1:8081/sales.out')
  FORMAT 'TEXT' ( DELIMITER '|' NULL ' ')
  DISTRIBUTED BY (txn_id);
```

Create a writable external web table that pipes output data received by the segments to an executable script named *to\_adreport\_etl.sh*:

```
CREATE WRITABLE EXTERNAL WEB TABLE campaign_out
(LIKE campaign)
EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
FORMAT 'TEXT' (DELIMITER '|');
```

Use the writable external table defined above to unload selected data:

```
INSERT INTO campaign_out SELECT * FROM campaign WHERE  
customer_id=123;
```

---

### Compatibility

`CREATE EXTERNAL TABLE` is a Greenplum Database extension. The SQL standard makes no provisions for external tables.

---

[CREATE TABLE AS](#), [CREATE TABLE](#), [COPY](#), [SELECT INTO](#), [INSERT](#)

---

## CREATE FUNCTION

Defines a new function.

---

### Synopsis

```
CREATE [OR REPLACE] FUNCTION name
    ( [ [argmode] [argname] argtype [, ...] ] )
    [ RETURNS { [ SETOF ] rettype
      | TABLE ([{ argname argtype | LIKE other table }
        [, ...])]
      } ]
    { LANGUAGE langname
      | IMMUTABLE | STABLE | VOLATILE
      | CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT
      | [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER
      | AS 'definition'
      | AS 'obj_file', 'link_symbol' } ...
    [ WITH ({ DESCRIBE = describe_function
      } [, ...] ) ]
```

---

### Description

CREATE FUNCTION defines a new function. CREATE OR REPLACE FUNCTION will either create a new function, or replace an existing definition.

The name of the new function must not match any existing function with the same argument types in the same schema. However, functions of different argument types may share a name (overloading).

To update the definition of an existing function, use CREATE OR REPLACE FUNCTION. It is not possible to change the name or argument types of a function this way (this would actually create a new, distinct function). Also, CREATE OR REPLACE FUNCTION will not let you change the return type of an existing function. To do that, you must drop and recreate the function. If you drop and then recreate a function, you will have to drop existing objects (rules, views, triggers, and so on) that refer to the old function. Use CREATE OR REPLACE FUNCTION to change a function definition without breaking objects that refer to the function.

For more information about creating functions, see the [User Defined Functions](#) section of the PostgreSQL documentation.

### Limited Use of VOLATILE and STABLE Functions

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as STABLE or VOLATILE cannot be executed at the segment level if it contains SQL or modifies the database in any way. For example, functions such as random() ortimeofday() are not allowed to execute on distributed data in Greenplum Database because they could potentially cause inconsistent data between the segment instances.

To ensure data consistency, `VOLATILE` and `STABLE` functions can safely be used in statements that are evaluated on and execute from the master. For example, the following statements are always executed on the master (statements without a `FROM` clause):

```
SELECT setval('myseq', 201);
SELECT foo();
```

In cases where a statement has a `FROM` clause containing a distributed table *and* the function used in the `FROM` clause simply returns a set of rows, execution may be allowed on the segments:

```
SELECT * FROM foo();
```

One exception to this rule are functions that return a table reference (`rangeFuncs`) or functions that use the `refCursor` data type. Note that you cannot return a `refcursor` from any kind of function in Greenplum Database.

---

## Parameters

### ***name***

The name (optionally schema-qualified) of the function to create.

### ***argmode***

The mode of an argument: either `IN`, `OUT`, or `INOUT`. If omitted, the default is `IN`.

### ***argname***

The name of an argument. Some languages (currently only PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation. But the name of an output argument is significant, since it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

### ***argtype***

The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types may be base, composite, or domain types, or may reference the type of a table column.

Depending on the implementation language it may also be allowed to specify pseudotypes such as `cstring`. Pseudotypes indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `tablename.columnname%TYPE`. Using this feature can sometimes help make a function independent of changes to the definition of a table.

***rettype***

The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or may reference the type of a table column. Depending on the implementation language it may also be allowed to specify pseudotypes such as `cstring`. If the function is not supposed to return a value, specify `void` as the return type.

When there are `OUT` or `INOUT` parameters, the `RETURNS` clause may be omitted. If present, it must agree with the result type implied by the output parameters: `RECORD` if there are multiple output parameters, or the same type as the single output parameter.

The `SETOF` modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `tablename.columnname%TYPE`.

***langname***

The name of the language that the function is implemented in. May be `SQL`, `C`, `internal`, or the name of a user-defined procedural language. See [CREATE LANGUAGE](#) for the procedural languages supported in Greenplum Database. For backward compatibility, the name may be enclosed by single quotes.

**IMMUTABLE**  
**STABLE**  
**VOLATILE**

These attributes inform the query optimizer about the behavior of the function. At most one choice may be specified. If none of these appear, `VOLATILE` is the default assumption. Since Greenplum Database currently has limited use of `VOLATILE` functions, if a function is truly `IMMUTABLE`, you must declare it as so to be able to use it without restrictions.

`IMMUTABLE` indicates that the function cannot modify the database and always returns the same result when given the same argument values. It does not do database lookups or otherwise use information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

`STABLE` indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter values (such as the current time zone), and so on. Also note that the *current\_timestamp* family of functions qualify as stable, since their values do not change within a transaction.

`VOLATILE` indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are `random()`, `curval()`, `timeofday()`. But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is `setval()`.

**CALLED ON NULL INPUT**  
**RETURNS NULL ON NULL INPUT**  
**STRICT**

**CALLED ON NULL INPUT** (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately.

**RETURNS NULL ON NULL INPUT** or **STRICT** indicates that the function always returns null whenever any of its arguments are null. If this parameter is specified, the function is not executed when there are null arguments; instead a null result is assumed automatically.

**[EXTERNAL] SECURITY INVOKER**  
**[EXTERNAL] SECURITY DEFINER**

**SECURITY INVOKER** (the default) indicates that the function is to be executed with the privileges of the user that calls it. **SECURITY DEFINER** specifies that the function is to be executed with the privileges of the user that created it. The key word **EXTERNAL** is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not just external ones.

#### ***definition***

A string constant defining the function; the meaning depends on the language. It may be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

#### ***obj\_file, link\_symbol***

This form of the **AS** clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string *obj\_file* is the name of the file containing the dynamically loadable object, and *link\_symbol* is the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined. It is recommended to locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter). This simplifies version upgrades if the new installation is at a different location.

#### ***describe\_function***

The name of a callback function to execute when a query that calls this function is parsed. The callback function returns a tuple descriptor that indicates the result type.

---

### **Notes**

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files. It is recommended to locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter) on all master segment instances in the Greenplum array.

The full SQL type syntax is allowed for input arguments and return value. However, some details of the type specification (such as the precision field for type *numeric*) are the responsibility of the underlying function implementation and are not recognized or enforced by the `CREATE FUNCTION` command.

Greenplum Database allows function overloading. The same name can be used for several different functions so long as they have distinct argument types. However, the C names of all functions must be different, so you must give overloaded C functions different C names (for example, use the argument types as part of the C names).

Two functions are considered the same if they have the same names and input argument types, ignoring any OUT parameters. Thus for example these declarations conflict:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, out text) ...
```

When repeated `CREATE FUNCTION` calls refer to the same object file, the file is only loaded once. To unload and reload the file, use the `LOAD` command.

To be able to define a function, the user must have the `USAGE` privilege on the language.

It is often helpful to use dollar quoting to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them. A dollar-quoted string constant consists of a dollar sign (\$), an optional tag of zero or more characters, another dollar sign, an arbitrary sequence of characters that makes up the string content, a dollar sign, the same tag that began this dollar quote, and a dollar sign. Inside the dollar-quoted string, single quotes, backslashes, or any character can be used without escaping. The string content is always written literally. For example, here are two different ways to specify the string “Dianne’s horse” using dollar quoting:

```
$$Dianne's horse$$
$SomeTag$Dianne's horse$SomeTag$
```

### Using Functions With Queries on Distributed Data

In some cases, Greenplum Database does not support using functions in a query where the data in a table specified in the `FROM` clause is distributed over Greenplum Database segments. As an example, this SQL query contains the function `func()`:

```
SELECT func(a) FROM table1;
```

The function is not supported for use in the query if all of the following conditions are met:

- The data of table `table1` is distributed over Greenplum Database segments.
- The function `func()` reads or modifies data from distributed tables.
- The function `func()` returns more than one row or takes an argument (`a`) that comes from `table1`.

If any of the conditions are not met, the function is supported. Specifically, the function is supported if any of the following conditions apply:

- The function `func()` does not access data from distributed tables, or accesses data that is only on the Greenplum Database master.
- The table `table1` is a master only table.
- The function `func()` returns only one row and only takes input arguments that are constant values. The function is supported if it can be changed to require no input arguments.

---

## Examples

A very simple addition function:

```
CREATE FUNCTION add(integer, integer) RETURNS integer
  AS 'select $1 + $2;'
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT;
```

Increment an integer, making use of an argument name, in PL/pgSQL:

```
CREATE OR REPLACE FUNCTION increment(i integer) RETURNS
integer AS $$
  BEGIN
    RETURN i + 1;
  END;
$$ LANGUAGE plpgsql;
```

Return a record containing multiple output parameters:

```
CREATE FUNCTION dup(in int, out f1 int, out f2 text)
  AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
  LANGUAGE SQL;
SELECT * FROM dup(42);
```

You can do the same thing more verbosely with an explicitly named composite type:

```
CREATE TYPE dup_result AS (f1 int, f2 text);
CREATE FUNCTION dup(int) RETURNS dup_result
  AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
  LANGUAGE SQL;
SELECT * FROM dup(42);
```

---

## Compatibility

`CREATE FUNCTION` is defined in SQL:1999 and later. The Greenplum Database version is similar but not fully compatible. The attributes are not portable, neither are the different available languages.

For compatibility with some other database systems, *argmode* can be written either before or after *argname*. But only the first way is standard-compliant.

---

## CREATE GROUP

Defines a new database role.

---

### Synopsis

```
CREATE GROUP name [ [WITH] option [ ... ] ]
```

where *option* can be:

SUPERUSER		NOSUPERUSER
CREATEDB		NOCREATEDB
CREATEROLE		NOCREATEROLE
CREATEUSER		NOCREATEUSER
INHERIT		NOINHERIT
LOGIN		NOLOGIN
[ ENCRYPTED   UNENCRYPTED ]		PASSWORD ' <i>password</i> '
VALID UNTIL ' <i>timestamp</i> '		
IN ROLE <i>rolename</i>		[, ...]
IN GROUP <i>rolename</i>		[, ...]
ROLE <i>rolename</i>		[, ...]
ADMIN <i>rolename</i>		[, ...]
USER <i>rolename</i>		[, ...]
SYSID <i>uid</i>		

---

### Description

As of Greenplum Database release 2.2, `CREATE GROUP` has been replaced by [CREATE ROLE](#), although it is still accepted for backwards compatibility.

---

### Compatibility

There is no `CREATE GROUP` statement in the SQL standard.

---

### See Also

[CREATE ROLE](#)

---

## CREATE INDEX

Defines a new index.

---

### Synopsis

```
CREATE [UNIQUE] INDEX name ON table
    [USING btree|bitmap|gist]
    ( {column | (expression)} [opclass] [, ...] )
    [ WITH ( FILLFACTOR = value ) ]
    [TABLESPACE tablespace]
    [WHERE predicate]
```

---

### Description

CREATE INDEX constructs an index on the specified table. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on `upper(col)` would allow the clause `WHERE upper(col) = 'JIM'` to use an index.

Greenplum Database provides the index methods B-tree, bitmap, and GiST. Users can also define their own index methods, but that is fairly complicated.

When the WHERE clause is present, a partial index is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet is most often selected, you can improve performance by creating an index on just that portion.

The expression used in the WHERE clause may refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Subqueries and aggregate expressions are also forbidden in WHERE. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be immutable. Their results must depend only on their arguments and never on any outside influence (such as the contents of another table or a parameter value). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or WHERE clause, remember to mark the function IMMUTABLE when you create it.

---

## Parameters

**UNIQUE**

Checks for duplicate values in the table when the index is created and each time data is added. Duplicate entries will generate an error. Unique indexes only apply to B-tree indexes. In Greenplum Database, unique indexes are allowed only if the columns of the index key are the same as (or a superset of) the Greenplum distribution key. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions.

***name***

The name of the index to be created. The index is always created in the same schema as its parent table.

***table***

The name (optionally schema-qualified) of the table to be indexed.

***btree* | *bitmap* | *gist***

The name of the index method to be used. Choices are *btree*, *bitmap*, and *gist*. The default method is *btree*.

***column***

The name of a column of the table on which to create the index. Only the B-tree, bitmap, and GiST index methods support multicolumn indexes.

***expression***

An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses may be omitted if the expression has the form of a function call.

***opclass***

The name of an operator class. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class (this operator class includes comparison functions for four-byte integers). In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, a complex-number data type could be sorted by either absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index.

**FILLFACTOR**

The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index's efficiency.

B-trees use a default fillfactor of 90, but any value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index's physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

### ***tablespace***

The tablespace in which to create the index. If not specified, the default tablespace is used.

### ***predicate***

The constraint expression for a partial index.

---

## **Notes**

UNIQUE indexes are allowed only if the index columns are the same as (or a superset of) the Greenplum distribution key columns. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions.

UNIQUE indexes are not allowed on append-optimized tables.

Indexes are not used for IS NULL clauses by default. The best way to use indexes in such cases is to create a partial index using an IS NULL predicate.

bitmap indexes perform best for columns that have between 100 and 100,000 distinct values. For a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Columns with fewer than 100 distinct values usually do not benefit much from any type of index. For example, a gender column with only two distinct values for male and female would not be a good candidate for an index.

Prior releases of Greenplum Database also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If USING rtree is specified, CREATE INDEX will interpret it as USING gist.

For more information on the GiST index type, refer to the [PostgreSQL documentation](#).

The use of hash and GIN indexes has been disabled in Greenplum Database.

---

## **Examples**

To create a B-tree index on the column *title* in the table *films*:

```
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create a bitmap index on the column *gender* in the table *employee*:

```
CREATE INDEX gender_bmp_idx ON employee USING bitmap
(gender);
```

To create an index on the expression *lower(title)*, allowing efficient case-insensitive searches:

```
CREATE INDEX lower_title_idx ON films ((lower(title)));
```

To create an index with non-default fill factor:

```
CREATE UNIQUE INDEX title_idx ON films (title) WITH  
(fillfactor = 70);
```

To create an index on the column *code* in the table *films* and have the index reside in the tablespace *indexspace*:

```
CREATE INDEX code_idx ON films(code) TABLESPACE indexspace;
```

---

## Compatibility

`CREATE INDEX` is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.

Greenplum Database does not support the concurrent creation of indexes (`CONCURRENTLY` keyword not supported).

---

## CREATE LANGUAGE

Defines a new procedural language.

---

### Synopsis

```
CREATE [PROCEDURAL] LANGUAGE name
CREATE [TRUSTED] [PROCEDURAL] LANGUAGE name
    HANDLER call_handler [VALIDATOR valfunction]
```

---

### Description

CREATE LANGUAGE registers a new procedural language with a Greenplum database. Subsequently, functions and trigger procedures can be defined in this new language. You must be a superuser to register a new language. The PL/pgSQL language is already registered in all databases by default.

CREATE LANGUAGE effectively associates the language name with a call handler that is responsible for executing functions written in that language. For a function written in a procedural language (a language other than C or SQL), the database server has no built-in knowledge about how to interpret the function's source code. The task is passed to a special handler that knows the details of the language. The handler could either do all the work of parsing, syntax analysis, execution, and so on or it could serve as a bridge between Greenplum Database and an existing implementation of a programming language. The handler itself is a C language function compiled into a shared object and loaded on demand, just like any other C function. There are currently four procedural language packages included in the standard Greenplum Database distribution: PL/pgSQL, PL/Perl, PL/Python, and PL/Java. A language handler has also been added for PL/R, but the PL/R language package is not pre-installed with Greenplum Database. See the section on [Procedural Languages](#) in the PostgreSQL documentation for more information on developing functions using these procedural languages.

The PL/Perl, PL/Java, and PL/R libraries require the correct versions of Perl, Java, and R to be installed, respectively.

On RHEL and SUSE platforms, download the appropriate extensions from the [EMC Download Center](#), then install the extensions using the Greenplum Package Manager (gppkg) utility to ensure that all dependencies are installed as well as the extensions. See the *Greenplum Database Utility Guide* for details about gppkg.

On Solaris platforms, installing dependencies is a manual process:

- For PL/Perl: ensure that the systems that run Greenplum Database (master and all segments) have a shared version of Perl installed. 64-bit systems require a 64-bit shared version of Perl. Solaris does not have a 64-bit shared version of Perl by default. Greenplum provides a 64-bit shared version of Perl for Solaris, available from the [EMC Download Center](#).

- For PL/Java, ensure that the systems that run Greenplum Database (master and all segments) have a JDK version 1.6 or higher installed. Add any Java archive (jar) files to `$GPHOME/lib/postgresql/java` and ensure they are listed in the `pljava_classpath` server configuration parameter. See the `PLJAVA_README` file (located in `$GPHOME/share/postgresql/pljava`) for more information on using PL/Java in Greenplum Database.
- For PL/R, ensure that the systems that run Greenplum Database (master and all segments) have the R language installed and the PL/R package library (`plr.so`) added to their Greenplum installation on all hosts. Greenplum provides compiled packages for R and PL/R that you can install.

There are two forms of the `CREATE LANGUAGE` command. In the first form, the user specifies the name of the desired language and the Greenplum Database server uses the `pg_pltemplate` system catalog to determine the correct parameters. In the second form, the user specifies the language parameters as well as the language name. You can use the second form to create a language that is not defined in `pg_pltemplate`.

When the server finds an entry in the `pg_pltemplate` catalog for the given language name, it will use the catalog data even if the command includes language parameters. This behavior simplifies loading of old dump files, which are likely to contain out-of-date information about language support functions.

---

## Parameters

### TRUSTED

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. Specifies that the call handler for the language is safe and does not offer an unprivileged user any functionality to bypass access restrictions. If this key word is omitted when registering the language, only users with the superuser privilege can use this language to create new functions.

### PROCEDURAL

This is a noise word.

### *name*

The name of the new procedural language. The language name is case insensitive. The name must be unique among the languages in the database. Built-in support is included for `plpgsql`, `plperl`, `plpython`, `plpythonu`, and `plr`. `plpgsql` is already installed by default in Greenplum Database.

### HANDLER *call\_handler*

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. The name of a previously registered function that will be called to execute the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Greenplum Database as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

**VALIDATOR *valfunction***

Ignored if the server has an entry for the specified language name in *pg\_pltemplate*. *valfunction* is the name of a previously registered function that will be called when a new function in the language is created, to validate the new function. If no validator function is specified, then a new function will not be checked when it is created. The validator function must take one argument of type *oid*, which will be the OID of the to-be-created function, and will typically return *void*.

A validator function would typically inspect the function body for syntactical correctness, but it can also look at other properties of the function, for example if the language cannot handle certain argument types. To signal an error, the validator function should use the *ereport()* function. The return value of the function is ignored.

---

**Notes**

The PL/pgSQL language is installed by default in Greenplum Database.

The system catalog *pg\_language* records information about the currently installed languages.

To create functions in a procedural language, a user must have the *USAGE* privilege for the language. By default, *USAGE* is granted to *PUBLIC* (everyone) for trusted languages. This may be revoked if desired.

Procedural languages are local to individual databases. However, a language can be installed into the *template1* database, which will cause it to be available automatically in all subsequently-created databases.

The call handler function and the validator function (if any) must already exist if the server does not have an entry for the language in *pg\_pltemplate*. But when there is an entry, the functions need not already exist; they will be automatically defined if not present in the database.

Any shared library that implements a language must be located in the same *LD\_LIBRARY\_PATH* location on all segment hosts in your Greenplum Database array.

---

**Examples**

The preferred way of creating any of the standard procedural languages:

```
CREATE LANGUAGE plpgsql;
CREATE LANGUAGE plr;
```

For a language not known in the *pg\_pltemplate* catalog:

```
CREATE FUNCTION plsample_call_handler() RETURNS
language_handler
AS '$libdir/plsample'
LANGUAGE C;
CREATE LANGUAGE plsample
HANDLER plsample_call_handler;
```

---

## Compatibility

`CREATE LANGUAGE` is a Greenplum Database extension.

---

## See Also

[ALTER LANGUAGE](#), [CREATE FUNCTION](#), [DROP LANGUAGE](#)

---

## CREATE OPERATOR

Defines a new operator.

---

### Synopsis

```
CREATE OPERATOR name (
    PROCEDURE = funcname
    [, LEFTARG = lefttype] [, RIGHTARG = righttype]
    [, COMMUTATOR = com_op] [, NEGATOR = neg_op]
    [, RESTRICT = res_proc] [, JOIN = join_proc]
    [, HASHES] [, MERGES]
    [, SORT1 = left_sort_op] [, SORT2 = right_sort_op]
    [, LTCMP = less_than_op] [, GTCMP = greater_than_op] )
```

---

### Description

CREATE OPERATOR defines a new operator. The user who defines an operator becomes its owner.

The operator name is a sequence of up to NAMEDATALEN-1 (63 by default) characters from the following list: + - \* / < > = ~ ! @ # % ^ & | ` ?

There are a few restrictions on your choice of name:

- -- and /\* cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multicharacter operator name cannot end in + or -, unless the name also contains at least one of these characters: ~ ! @ # % ^ & | ` ?

For example, @- is an allowed operator name, but \*- is not. This restriction allows Greenplum Database to parse SQL-compliant commands without requiring spaces between tokens.

The operator != is mapped to <> on input, so these two names are always equivalent.

At least one of LEFTARG and RIGHTARG must be defined. For binary operators, both must be defined. For right unary operators, only LEFTARG should be defined, while for left unary operators only RIGHTARG should be defined.

The *funcname* procedure must have been previously defined using CREATE FUNCTION, must be IMMUTABLE, and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

The other clauses specify optional operator optimization clauses. These clauses should be provided whenever appropriate to speed up queries that use the operator. But if you provide them, you must be sure that they are correct. Incorrect use of an optimization clause can result in server process crashes, subtly wrong output, or other unexpected results. You can always leave out an optimization clause if you are not sure about it.

---

## Parameters

***name***

The (optionally schema-qualified) name of the operator to be defined. Two operators in the same schema can have the same name if they operate on different data types.

***funcname***

The function used to implement this operator (must be an IMMUTABLE function).

***lefttype***

The data type of the operator's left operand, if any. This option would be omitted for a left-unary operator.

***righttype***

The data type of the operator's right operand, if any. This option would be omitted for a right-unary operator.

***com\_op***

The optional `COMMUTATOR` clause names an operator that is the commutator of the operator being defined. We say that operator A is the commutator of operator B if  $(x \ A \ y)$  equals  $(y \ B \ x)$  for all possible input values  $x, y$ . Notice that B is also the commutator of A. For example, operators `<` and `>` for a particular data type are usually each others commutators, and operator `+` is usually commutative with itself. But operator `-` is usually not commutative with anything. The left operand type of a commutable operator is the same as the right operand type of its commutator, and vice versa. So the name of the commutator operator is all that needs to be provided in the `COMMUTATOR` clause.

***neg\_op***

The optional `NEGATOR` clause names an operator that is the negator of the operator being defined. We say that operator A is the negator of operator B if both return Boolean results and  $(x \ A \ y)$  equals `NOT (x B y)` for all possible inputs  $x, y$ . Notice that B is also the negator of A. For example, `<` and `>=` are a negator pair for most data types. An operator's negator must have the same left and/or right operand types as the operator to be defined, so only the operator name need be given in the `NEGATOR` clause.

***res\_proc***

The optional `RESTRICT` names a restriction selectivity estimation function for the operator. Note that this is a function name, not an operator name. `RESTRICT` clauses only make sense for binary operators that return `boolean`. The idea behind a restriction selectivity estimator is to guess what fraction of the rows in a table will satisfy a `WHERE`-clause condition of the form:

```
column OP constant
```

for the current operator and a particular constant value. This assists the optimizer by giving it some idea of how many rows will be eliminated by `WHERE` clauses that have this form.

You can usually just use one of the following system standard estimator functions for many of your own operators:

```
eqsel for =
neqsel for <>
scalarltsel for < or <=
scalargtsel for > or >=
```

### ***join\_proc***

The optional `JOIN` clause names a join selectivity estimation function for the operator. Note that this is a function name, not an operator name. `JOIN` clauses only make sense for binary operators that return `boolean`. The idea behind a join selectivity estimator is to guess what fraction of the rows in a pair of tables will satisfy a `WHERE`-clause condition of the form

```
table1.column1 OP table2.column2
```

for the current operator. This helps the optimizer by letting it figure out which of several possible join sequences is likely to take the least work.

You can usually just use one of the following system standard join selectivity estimator functions for many of your own operators:

```
eqjoinssel for =
neqjoinssel for <>
scalarltjoinssel for < or <=
scalargtjoinssel for > or >=
areajoinssel for 2D area-based comparisons
positionjoinssel for 2D position-based comparisons
contjoinssel for 2D containment-based comparisons
```

### **HASHES**

The optional `HASHES` clause tells the system that it is permissible to use the hash join method for a join based on this operator. `HASHES` only makes sense for a binary operator that returns `boolean`. The hash join operator can only return true for pairs of left and right values that hash to the same hash code. If two values get put in different hash buckets, the join will never compare them at all, implicitly assuming that the result of the join operator must be false. So it never makes sense to specify `HASHES` for operators that do not represent equality.

To be marked `HASHES`, the join operator must appear in a hash index operator class. Attempts to use the operator in hash joins will fail at run time if no such operator class exists. The system needs the operator class to find the data-type-specific hash function for the operator's input data type. You must also supply a suitable hash

function before you can create the operator class. Care should be exercised when preparing a hash function, because there are machine-dependent ways in which it might fail to do the right thing.

## MERGES

The **MERGES** clause, if present, tells the system that it is permissible to use the merge-join method for a join based on this operator. **MERGES** only makes sense for a binary operator that returns **boolean**, and in practice the operator must represent equality for some data type or pair of data types.

Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the same place in the sort order. In practice this means that the join operator must behave like equality. It is possible to merge-join two distinct data types so long as they are logically compatible. For example, the **smallint-versus-integer** equality operator is merge-joinable. We only need sorting operators that will bring both data types into a logically compatible sequence.

Execution of a merge join requires that the system be able to identify four operators related to the merge-join equality operator: less-than comparison for the left operand data type, less-than comparison for the right operand data type, less-than comparison between the two data types, and greater-than comparison between the two data types. It is possible to specify these operators individually by name, as the **SORT1**, **SORT2**, **LTCMP**, and **GTCMP** options respectively. The system will fill in the default names if any of these are omitted when **MERGES** is specified.

### *left\_sort\_op*

If this operator can support a merge join, the less-than operator that sorts the left-hand data type of this operator. **<** is the default if not specified.

### *right\_sort\_op*

If this operator can support a merge join, the less-than operator that sorts the right-hand data type of this operator. **<** is the default if not specified.

### *less\_than\_op*

If this operator can support a merge join, the less-than operator that compares the input data types of this operator. **<** is the default if not specified.

### *greater\_than\_op*

If this operator can support a merge join, the greater-than operator that compares the input data types of this operator. **>** is the default if not specified.

To give a schema-qualified operator name in optional arguments, use the **OPERATOR()** syntax, for example:

```
COMMUTATOR = OPERATOR(myschema.===) ,
```

---

## Notes

Any functions used to implement the operator must be defined as **IMMUTABLE**.

---

## Examples

Here is an example of creating an operator for adding two complex numbers, assuming we have already created the definition of type `complex`. First define the function that does the work, then define the operator:

```
CREATE FUNCTION complex_add(complex, complex)
  RETURNS complex
  AS 'filename', 'complex_add'
  LANGUAGE C IMMUTABLE STRICT;
CREATE OPERATOR + (
  leftarg = complex,
  rightarg = complex,
  procedure = complex_add,
  commutator = +
);
```

To use this operator in a query:

```
SELECT (a + b) AS c FROM test_complex;
```

---

## Compatibility

`CREATE OPERATOR` is a Greenplum Database language extension. The SQL standard does not provide for user-defined operators.

---

## See Also

[CREATE FUNCTION](#), [CREATE TYPE](#), [ALTER OPERATOR](#), [DROP OPERATOR](#)

---

## CREATE OPERATOR CLASS

Defines a new operator class.

---

### Synopsis

```
CREATE OPERATOR CLASS name [DEFAULT] FOR TYPE data_type
  USING index_method AS
  {
    OPERATOR strategy_number op_name [(op_type, op_type)] [RECHECK]
    | FUNCTION support_number funcname (argument_type [, ...] )
    | STORAGE storage_type
  } [, ... ]
```

---

### Description

CREATE OPERATOR CLASS creates a new operator class. An operator class defines how a particular data type can be used with an index. The operator class specifies that certain operators will fill particular roles or strategies for this data type and this index method. The operator class also specifies the support procedures to be used by the index method when the operator class is selected for an index column. All the operators and functions used by an operator class must be defined before the operator class is created. Any functions used to implement the operator class must be defined as IMMUTABLE.

CREATE OPERATOR CLASS does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator class.

You must be a superuser to create an operator class.

---

### Parameters

#### *name*

The (optionally schema-qualified) name of the operator class to be defined. Two operator classes in the same schema can have the same name only if they are for different index methods.

#### DEFAULT

Makes the operator class the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.

#### *data\_type*

The column data type that this operator class is for.

#### *index\_method*

The name of the index method this operator class is for. Choices are `btree`, `bitmap`, and `gist`.

***strategy\_number***

The operators associated with an operator class are identified by *strategy numbers*, which serve to identify the semantics of each operator within the context of its operator class. For example, B-trees impose a strict ordering on keys, lesser to greater, and so operators like *less than* and *greater than or equal to* are interesting with respect to a B-tree. These strategies can be thought of as generalized operators. Each operator class specifies which actual operator corresponds to each strategy for a particular data type and interpretation of the index semantics. The corresponding strategy numbers for each index method are as follows:

**Table 1.1** B-tree and Bitmap Strategies

Operation	Strategy Number
less than	1
less than or equal	2
equal	3
greater than or equal	4
greater than	5

**Table 1.2** GiST Two-Dimensional Strategies (R-Tree)

Operation	Strategy Number
strictly left of	1
does not extend to right of	2
overlaps	3
does not extend to left of	4
strictly right of	5
same	6
contains	7
contained by	8
does not extend above	9
strictly below	10
strictly above	11
does not extend below	12

***operator\_name***

The name (optionally schema-qualified) of an operator associated with the operator class.

***op\_type***

The operand data type(s) of an operator, or *NONE* to signify a left-uniary or right-uniary operator. The operand data types may be omitted in the normal case where they are the same as the operator class data type.

**RECHECK**

If present, the index is “lossy” for this operator, and so the rows retrieved using the index must be rechecked to verify that they actually satisfy the qualification clause involving this operator.

***support\_number***

Index methods require additional support routines in order to work. These operations are administrative routines used internally by the index methods. As with strategies, the operator class identifies which specific functions should play each of these roles for a given data type and semantic interpretation. The index method defines the set of functions it needs, and the operator class identifies the correct functions to use by assigning them to the *support function numbers* as follows:

**Table 1.3** B-tree and Bitmap Support Functions

Function	Support Number
Compare two keys and return an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second.	1

**Table 1.4** GiST Support Functions

Function	Support Number
consistent - determine whether key satisfies the query qualifier.	1
union - compute union of a set of keys.	2
compress - compute a compressed representation of a key or value to be indexed.	3
decompress - compute a decompressed representation of a compressed key.	4
penalty - compute penalty for inserting new key into subtree with given subtree's key.	5
picksplit - determine which entries of a page are to be moved to the new page and compute the union keys for resulting pages.	6
equal - compare two keys and return true if they are equal.	7

***funcname***

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator class.

***argument\_types***

The parameter data type(s) of the function.

***storage\_type***

The data type actually stored in the index. Normally this is the same as the column data type, but the GiST index method allows it to be different. The `STORAGE` clause must be omitted unless the index method allows a different type to be used.

---

## Notes

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is the same as granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Any functions used to implement the operator class must be defined as `IMMUTABLE`.

---

## Examples

The following example command defines a GiST index operator class for the data type `_int4` (array of `int4`):

```
CREATE OPERATOR CLASS gist__int_ops
  DEFAULT FOR TYPE _int4 USING gist AS
    OPERATOR 3 &&,
    OPERATOR 6 = RECHECK,
    OPERATOR 7 @>,
    OPERATOR 8 <@,
    OPERATOR 20 @@ (_int4, query_int),
    FUNCTION 1 g_int_consistent (internal, _int4, int4),
    FUNCTION 2 g_int_union (bytea, internal),
    FUNCTION 3 g_int_compress (internal),
    FUNCTION 4 g_int_decompress (internal),
    FUNCTION 5 g_int_penalty (internal, internal, internal),
    FUNCTION 6 g_int_picksplit (internal, internal),
    FUNCTION 7 g_int_same (_int4, _int4, internal);
```

---

## Compatibility

`CREATE OPERATOR CLASS` is a Greenplum Database extension. There is no `CREATE OPERATOR CLASS` statement in the SQL standard.

---

## See Also

[ALTER OPERATOR CLASS](#), [DROP OPERATOR CLASS](#), [CREATE FUNCTION](#)

## CREATE RESOURCE QUEUE

Defines a new resource queue.

### Synopsis

```
CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])
```

where *queue\_attribute* is:

```
    ACTIVE_STATEMENTS=integer
    [ MAX_COST=float [COST_OVERCOMMIT={TRUE|FALSE}] ]
    [ MIN_COST=float ]
    [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
    [ MEMORY_LIMIT='memory_units' ]
|  MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
    [ ACTIVE_STATEMENTS=integer ]
    [ MIN_COST=float ]
    [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
    [ MEMORY_LIMIT='memory_units' ]
```

### Description

Creates a new resource queue for Greenplum Database workload management. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). Only a superuser can create a resource queue.

Resource queues with an `ACTIVE_STATEMENTS` threshold set a maximum limit on the number of queries that can be executed by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that can be executed by roles assigned to that queue. Cost is measured in the *estimated total cost* for the query as determined by the Greenplum Database query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically executed on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). If a resource queue is limited based on a cost threshold, then the administrator can allow `COST_OVERCOMMIT=TRUE` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run. Specifying a value for `MIN_COST` allows the administrator to define a cost for small queries that will be exempt from resource queueing.

If a value is not defined for `ACTIVE_STATEMENTS` or `MAX_COST`, it is set to -1 by default (meaning no limit). After defining a resource queue, you must assign roles to the queue using the [ALTER ROLE](#) or [CREATE ROLE](#) command.

You can optionally assign a `PRIORITY` to a resource queue to control the relative share of available CPU resources used by queries associated with the queue in relation to other resource queues. If a value is not defined for `PRIORITY`, queries associated with the queue have a default priority of `MEDIUM`.

Resource queues with an optional `MEMORY_LIMIT` threshold set a maximum limit on the amount of memory that all queries submitted through a resource queue can consume on a segment host. This determines the total amount of memory that all worker processes of a query can consume on a segment host during query execution. Greenplum recommends that `MEMORY_LIMIT` be used in conjunction with `ACTIVE_STATEMENTS` rather than with `MAX_COST`. The default amount of memory allotted per query on statement-based queues is: `MEMORY_LIMIT / ACTIVE_STATEMENTS`. The default amount of memory allotted per query on cost-based queues is: `MEMORY_LIMIT * (query_cost / MAX_COST)`.

The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded. For example, to allocate more memory to a particular query:

```
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

The `MEMORY_LIMIT` value for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, memory allocations can be oversubscribed. However, queries can be cancelled during execution if the segment host memory limit specified in `gp_vmem_protect_limit` is exceeded.

For information about `statement_mem`, `max_statement`, and `gp_vmem_protect_limit`, see [“Server Configuration Parameters”](#) on page 476.

---

## Parameters

### ***name***

The name of the resource queue.

### ***ACTIVE\_STATEMENTS integer***

Resource queues with an `ACTIVE_STATEMENTS` threshold limit the number of queries that can be executed by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

### ***MEMORY\_LIMIT 'memory\_units'***

Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum, however the upper boundary at query execution time is limited by the physical memory of a segment host. The default is no limit (-1).

**MAX\_COST float**

Resource queues with a MAX\_COST threshold set a maximum limit on the total cost of queries that can be executed by roles assigned to that queue. Cost is measured in the *estimated total cost* for the query as determined by the Greenplum Database query planner (as shown in the EXPLAIN output for a query). Therefore, an administrator must be familiar with the queries typically executed on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for MAX\_COST is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

**COST\_OVERCOMMIT boolean**

If a resource queue is limited based on MAX\_COST, then the administrator can allow COST\_OVERCOMMIT (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If COST\_OVERCOMMIT=FALSE is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

**MIN\_COST float**

The minimum query cost limit of what is considered a small query. Queries with a cost under this limit will not be queued and run immediately. Cost is measured in the *estimated total cost* for the query as determined by the Greenplum Database query planner (as shown in the EXPLAIN output for a query). Therefore, an administrator must be familiar with the queries typically executed on the system in order to set an appropriate cost for what is considered a small query. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for MIN\_COST is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

**PRIORITY={MIN | LOW | MEDIUM | HIGH | MAX}**

Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are executed. If no priority is specified, queries associated with the queue have a priority of MEDIUM.

---

**Notes**

Use the *gp\_toolkit.gp\_resqueue\_status* system view to see the limit settings and current status of a resource queue:

```
SELECT * from gp_toolkit.gp_resqueue_status WHERE
rsqname='queue_name';
```

There is also another system view named *pg\_stat\_resqueues* which shows statistical metrics for a resource queue over time. To use this view, however, you must enable the *stats\_queue\_level* server configuration parameter. See the *Greenplum Database Database Administrator Guide* for more information about using resource queues.

CREATE RESOURCE QUEUE cannot be run within a transaction.

---

## Examples

Create a resource queue with an active query limit of 20:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Create a resource queue with an active query limit of 20 and a total memory limit of 2000MB (each query will be allocated 100MB of segment host memory at execution time):

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20,
MEMORY_LIMIT='2000MB');
```

Create a resource queue with a query cost limit of 3000.0:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3000.0);
```

Create a resource queue with a query cost limit of  $3^{10}$  (or 30000000000.0) and do not allow overcommit. Allow small queries with a cost under 500 to run immediately:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10,
COST_OVERCOMMIT=FALSE, MIN_COST=500.0);
```

Create a resource queue with both an active query limit and a query cost limit:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=30,
MAX_COST=5000.00);
```

Create a resource queue with an active query limit of 5 and a maximum priority setting:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=5,
PRIORITY=MAX);
```

---

## Compatibility

CREATE RESOURCE QUEUE is a Greenplum Database extension. There is no provision for resource queues or workload management in the SQL standard.

---

## See Also

[ALTER ROLE](#), [CREATE ROLE](#), [ALTER RESOURCE QUEUE](#), [DROP RESOURCE QUEUE](#)

---

## CREATE ROLE

Defines a new database role (user or group).

---

### Synopsis

```
CREATE ROLE name [[WITH] option [ ... ]]
```

where *option* can be:

```

    SUPERUSER | NOSUPERUSER
  | CREATEDB | NOCREATEDB
  | CREATEROLE | NOCREATEROLE
  | CREATEEXTTABLE | NOCREATEEXTTABLE
  | [ ( attribute='value'[, ...] ) ]
      where attributes and values are:
      type='readable'|'writable'
      protocol='gpfdist'|'http'
  | INHERIT | NOINHERIT
  | LOGIN | NOLOGIN
  | CONNECTION LIMIT conlimit
  | [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
  | VALID UNTIL 'timestamp'
  | IN ROLE rolename [, ...]
  | ROLE rolename [, ...]
  | ADMIN rolename [, ...]
  | RESOURCE QUEUE queue_name
  | [ DENY deny_point ]
  | [ DENY BETWEEN deny_point AND deny_point]
```

---

### Description

CREATE ROLE adds a new role to a Greenplum Database system. A role is an entity that can own database objects and have database privileges. A role can be considered a user, a group, or both depending on how it is used. You must have CREATEROLE privilege or be a database superuser to use this command.

Note that roles are defined at the system-level and are valid for all databases in your Greenplum Database system.

---

### Parameters

***name***

The name of the new role.

**SUPERUSER  
NOSUPERUSER**

If **SUPERUSER** is specified, the role being defined will be a superuser, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed. You must yourself be a superuser to create a new superuser. **NOSUPERUSER** is the default.

**CREATEDB  
NOCREATEDB**

If **CREATEDB** is specified, the role being defined will be allowed to create new databases. **NOCREATEDB** (the default) will deny a role the ability to create databases.

**CREATEROLE  
NOCREATEROLE**

If **CREATEDB** is specified, the role being defined will be allowed to create new roles, alter other roles, and drop other roles. **NOCREATEROLE** (the default) will deny a role the ability to create roles or modify roles other than their own.

**CREATEEXTTABLE  
NOCREATEEXTTABLE**

If **CREATEEXTTABLE** is specified, the role being defined is allowed to create external tables. The default type is `readable` and the default protocol is `gpfdist` if not specified. **NOCREATEEXTTABLE** (the default) denies the role the ability to create external tables. Note that external tables that use the `file` or `execute` protocols can only be created by superusers.

**INHERIT  
NOINHERIT**

If specified, **INHERIT** (the default) allows the role to use whatever database privileges have been granted to all roles it is directly or indirectly a member of. With **NOINHERIT**, membership in another role only grants the ability to `SET ROLE` to that other role.

**LOGIN  
NOLOGIN**

If specified, **LOGIN** allows a role to log in to a database. A role having the **LOGIN** attribute can be thought of as a user. Roles with **NOLOGIN** (the default) are useful for managing database privileges, and can be thought of as groups.

**CONNECTION LIMIT *conlimit***

The number maximum of concurrent connections this role can make. The default of `-1` means there is no limitation.

**PASSWORD *password***

Sets the user password for roles with the **LOGIN** attribute. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as `PASSWORD NULL`.

**ENCRYPTED**  
**UNENCRYPTED**

These key words control whether the password is stored encrypted in the system catalogs. (If neither is specified, the default behavior is determined by the configuration parameter *password\_encryption*.) If the presented password string is already in MD5-encrypted format, then it is stored encrypted as-is, regardless of whether **ENCRYPTED** or **UNENCRYPTED** is specified (since the system cannot decrypt the specified encrypted password string). This allows reloading of encrypted passwords during dump/restore.

Note that older clients may lack support for the MD5 authentication mechanism that is needed to work with passwords that are stored encrypted.

**VALID UNTIL 'timestamp'**

The **VALID UNTIL** clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will never expire.

**IN ROLE rolename**

Adds the new role as a member of the named roles. Note that there is no option to add the new role as an administrator; use a separate **GRANT** command to do that.

**ROLE rolename**

Adds the named roles as members of this role, making this new role a group.

**ADMIN rolename**

The **ADMIN** clause is like **ROLE**, but the named roles are added to the new role **WITH ADMIN OPTION**, giving them the right to grant membership in this role to others.

**RESOURCE QUEUE queue\_name**

The name of the resource queue to which the new user-level role is to be assigned. Only roles with **LOGIN** privilege can be assigned to a resource queue. The special keyword **NONE** means that the role is assigned to the default resource queue. A role can only belong to one resource queue.

**DENY deny\_point****DENY BETWEEN deny\_point AND deny\_point**

The **DENY** and **DENY BETWEEN** keywords set time-based constraints that are enforced at login. **DENY** sets a day or a day and time to deny access. **DENY BETWEEN** sets an interval during which access is denied. Both use the parameter *deny\_point* that has the following format:

```
DAY day [ TIME 'time' ]
```

The two parts of the *deny\_point* parameter use the following formats:

For day:

```
{ 'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' | 'Friday' |  
'Saturday' | 0-6 }
```

For time:

```
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM } }
```

The `DENY BETWEEN` clause uses two *deny\_point* parameters.

```
DENY BETWEEN deny_point AND deny_point
```

For more information and examples about time-based constraints, see the *Greenplum Database Database Administrator Guide*.

---

## Notes

The preferred way to add and remove role members (manage groups) is to use [GRANT](#) and [REVOKE](#).

The `VALID UNTIL` clause defines an expiration time for a password only, not for the role. The expiration time is not enforced when logging in using a non-password-based authentication method.

The `INHERIT` attribute governs inheritance of grantable privileges (access privileges for database objects and role memberships). It does not apply to the special role attributes set by `CREATE ROLE` and `ALTER ROLE`. For example, being a member of a role with `CREATEDB` privilege does not immediately grant the ability to create databases, even if `INHERIT` is set.

The `INHERIT` attribute is the default for reasons of backwards compatibility. In prior releases of Greenplum Database, users always had access to all privileges of groups they were members of. However, `NOINHERIT` provides a closer match to the semantics specified in the SQL standard.

Be careful with the `CREATEROLE` privilege. There is no concept of inheritance for the privileges of a `CREATEROLE`-role. That means that even if a role does not have a certain privilege but is allowed to create other roles, it can easily create another role with different privileges than its own (except for creating roles with superuser privileges). For example, if a role has the `CREATEROLE` privilege but not the `CREATEDB` privilege, it can create a new role with the `CREATEDB` privilege. Therefore, regard roles that have the `CREATEROLE` privilege as almost-superuser-roles.

The `CONNECTION LIMIT` option is never enforced for superusers.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear-text, and it might also be logged in the client's command history or the server log. The client program `createuser`, however, transmits the password encrypted. Also, `psql` contains a command `\password` that can be used to safely change the password later.

---

## Examples

Create a role that can log in, but don't give it a password:

```
CREATE ROLE jonathan LOGIN;
```

Create a role that belongs to a resource queue:

```
CREATE ROLE jonathan LOGIN RESOURCE QUEUE poweruser;
```

Create a role with a password that is valid until the end of 2009 (`CREATE USER` is the same as `CREATE ROLE` except that it implies `LOGIN`):

```
CREATE USER joelle WITH PASSWORD 'jw8s0F4' VALID UNTIL
'2010-01-01';
```

Create a role that can create databases and manage other roles:

```
CREATE ROLE admin WITH CREATEDB CREATEROLE;
```

Create a role that does not allow login access on Sundays:

```
CREATE ROLE user3 DENY DAY 'Sunday';
```

---

## Compatibility

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by the database implementation. In Greenplum Database users and roles are unified into a single type of object. Roles therefore have many more optional attributes than they do in the standard.

`CREATE ROLE` is in the SQL standard, but the standard only requires the syntax:

```
CREATE ROLE name [WITH ADMIN rolename]
```

Allowing multiple initial administrators, and all the other options of `CREATE ROLE`, are Greenplum Database extensions.

The behavior specified by the SQL standard is most closely approximated by giving users the `NOINHERIT` attribute, while roles are given the `INHERIT` attribute.

---

## CREATE RULE

Defines a new rewrite rule.

---

### Synopsis

```
CREATE [OR REPLACE] RULE name AS ON event
  TO table [WHERE condition]
  DO [ALSO | INSTEAD] { NOTHING | command | (command; command
  ...) }
```

---

### Description

CREATE RULE defines a new rule applying to a specified table or view. CREATE OR REPLACE RULE will either create a new rule, or replace an existing rule of the same name for the same table.

The Greenplum Database rule system allows one to define an alternate action to be performed on insertions, updates, or deletions in database tables. A rule causes additional or alternate commands to be executed when a given command on a given table is executed. Rules can be used on views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the commands starts. It does not operate independently for each physical row as does a trigger.

ON SELECT rules must be unconditional INSTEAD rules and must have actions that consist of a single SELECT command. Thus, an ON SELECT rule effectively turns the table into a view, whose visible contents are the rows returned by the rule's SELECT command rather than whatever had been stored in the table (if anything). It is considered better style to write a CREATE VIEW command than to create a real table and define an ON SELECT rule for it.

You can create the illusion of an updatable view by defining ON INSERT, ON UPDATE, and ON DELETE rules to replace update actions on the view with appropriate updates on other tables. If you want to support INSERT RETURNING and so on, then be sure to put a suitable RETURNING clause into each of these rules.

Rules are also helpful for managing partitioned tables. You can define ON INSERT rules on the parent table to route inserted rows to the correct partitioned child table. Note that rules do not work for COPY commands.

There is a catch if you try to use conditional rules for view updates: there must be an unconditional INSTEAD rule for each action you wish to allow on the view. If the rule is conditional, or is not INSTEAD, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all the useful cases in conditional rules, add an unconditional DO INSTEAD NOTHING rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non-INSTEAD; in the cases where they are applied, they add to the default INSTEAD NOTHING action. (This method does not currently work to support RETURNING queries, however.)

---

**Parameters*****name***

The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

***event***

The event is one of SELECT, INSERT, UPDATE, or DELETE.

***table***

The name (optionally schema-qualified) of the table or view the rule applies to.

***condition***

Any SQL conditional expression (returning boolean). The condition expression may not refer to any tables except NEW and OLD, and may not contain aggregate functions. NEW and OLD refer to values in the referenced table. NEW is valid in ON INSERT and ON UPDATE rules to refer to the new row being inserted or updated. OLD is valid in ON UPDATE and ON DELETE rules to refer to the existing row being updated or deleted.

**INSTEAD**

INSTEAD indicates that the commands should be executed instead of the original command.

**ALSO**

ALSO indicates that the commands should be executed in addition to the original command. If neither ALSO nor INSTEAD is specified, ALSO is the default.

***command***

The command or commands that make up the rule action. Valid commands are SELECT, INSERT, UPDATE, or DELETE. The special table names NEW and OLD may be used to refer to values in the referenced table. NEW is valid in ON INSERT and ON UPDATE rules to refer to the new row being inserted or updated. OLD is valid in ON UPDATE and ON DELETE rules to refer to the existing row being updated or deleted.

---

**Notes**

You must be the owner of a table to create or change rules for it.

In a rule for INSERT, UPDATE, or DELETE on a view, you can add a RETURNING clause that emits the view's columns. This clause will be used to compute the outputs if the rule is triggered by an INSERT RETURNING, UPDATE RETURNING, or DELETE RETURNING command respectively. When the rule is triggered by a command without RETURNING, the rule's RETURNING clause will be ignored. The current implementation allows only unconditional INSTEAD rules to contain RETURNING; furthermore there can be at most one RETURNING clause among all the rules for the same event. (This

ensures that there is only one candidate RETURNING clause to be used to compute the results.) RETURNING queries on the view will be rejected if there is no RETURNING clause in any available rule.

It is very important to take care to avoid circular rules. Recursive rules are not validated at rule create time, but will report an error at execution time.

---

## Examples

Create a rule that inserts rows into the child table *b2001* when a user tries to insert into the partitioned parent table *rank*:

```
CREATE RULE b2001 AS ON INSERT TO rank WHERE gender='M' and
year='2001' DO INSTEAD INSERT INTO b2001 VALUES (NEW.id,
NEW.rank, NEW.year, NEW.gender, NEW.count);
```

---

## Compatibility

CREATE RULE is a Greenplum Database language extension, as is the entire query rewrite system.

---

---

## CREATE SCHEMA

Defines a new schema.

---

### Synopsis

```
CREATE SCHEMA schema_name [AUTHORIZATION username]
[schema_element [ ... ]]

CREATE SCHEMA AUTHORIZATION rolename [schema_element [ ... ]]
```

---

### Description

CREATE SCHEMA enters a new schema into the current database. The schema name must be distinct from the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and operators) whose names may duplicate those of other objects existing in other schemas. Named objects are accessed either by qualifying their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). A CREATE command specifying an unqualified object name creates the object in the current schema (the one at the front of the search path, which can be determined with the function `current_schema()`).

Optionally, CREATE SCHEMA can include subcommands to create objects within the new schema. The subcommands are treated essentially the same as separate commands issued after creating the schema, except that if the AUTHORIZATION clause is used, all the created objects will be owned by that role.

---

### Parameters

#### *schema\_name*

The name of a schema to be created. If this is omitted, the user name is used as the schema name. The name cannot begin with `pg_`, as such names are reserved for system catalog schemas.

#### *rolename*

The name of the role who will own the schema. If omitted, defaults to the role executing the command. Only superusers may create schemas owned by roles other than themselves.

#### *schema\_element*

An SQL statement defining an object to be created within the schema. Currently, only CREATE TABLE, CREATE VIEW, CREATE INDEX, CREATE SEQUENCE, CREATE TRIGGER and GRANT are accepted as clauses within CREATE SCHEMA. Other kinds of objects may be created in separate commands after the schema is created.

---

## Notes

To create a schema, the invoking user must have the `CREATE` privilege for the current database or be a superuser.

---

## Examples

Create a schema:

```
CREATE SCHEMA myschema;
```

Create a schema for role *joe* (the schema will also be named *joe*):

```
CREATE SCHEMA AUTHORIZATION joe;
```

---

## Compatibility

The SQL standard allows a `DEFAULT CHARACTER SET` clause in `CREATE SCHEMA`, as well as more subcommand types than are presently accepted by Greenplum Database.

The SQL standard specifies that the subcommands in `CREATE SCHEMA` may appear in any order. The present Greenplum Database implementation does not handle all cases of forward references in subcommands; it may sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. Greenplum Database allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the `CREATE` privilege on the schema to someone else.

## CREATE SEQUENCE

Defines a new sequence generator.

---

### Synopsis

```
CREATE [TEMPORARY | TEMP] SEQUENCE name
      [INCREMENT [BY] value]
      [MINVALUE minvalue | NO MINVALUE]
      [MAXVALUE maxvalue | NO MAXVALUE]
      [START [ WITH ] start]
      [CACHE cache]
      [[NO] CYCLE]
      [OWNED BY { table.column | NONE }]
```

---

### Description

CREATE SEQUENCE creates a new sequence number generator. This involves creating and initializing a new special single-row table. The generator will be owned by the user issuing the command.

If a schema name is given, then the sequence is created in the specified schema. Otherwise it is created in the current schema. Temporary sequences exist in a special schema, so a schema name may not be given when creating a temporary sequence. The sequence name must be distinct from the name of any other sequence, table, index, or view in the same schema.

After a sequence is created, you use the `nextval` function to operate on the sequence. For example, to insert a row into a table that gets the next value of a sequence:

```
INSERT INTO distributors VALUES (nextval('myserial'),
                                'acme');
```

You can also use the function `setval` to operate on a sequence, but only for queries that do not operate on distributed data. For example, the following query is allowed because it resets the sequence counter value for the sequence generator process on the master:

```
SELECT setval('myserial', 201);
```

But the following query will be rejected in Greenplum Database because it operates on distributed data:

```
INSERT INTO product VALUES (setval('myserial', 201),
                             'gizmo');
```

In a regular (non-distributed) database, functions that operate on the sequence go to the local sequence table to get values as they are needed. In Greenplum Database, however, keep in mind that each segment is its own distinct database process. Therefore the segments need a single point of truth to go for sequence values so that all segments get incremented correctly and the sequence moves forward in the right order. A sequence server process runs on the master and is the point-of-truth for a sequence in a Greenplum distributed database. Segments get sequence values at runtime from the master.

Because of this distributed sequence design, there are some limitations on the functions that operate on a sequence in Greenplum Database:

- `lastval` and `currval` functions are not supported.
- `setval` can only be used to set the value of the sequence generator on the master, it cannot be used in subqueries to update records on distributed table data.
- `nextval` sometimes grabs a block of values from the master for a segment to use, depending on the query. So values may sometimes be skipped in the sequence if all of the block turns out not to be needed at the segment level. Note that a regular PostgreSQL database does this too, so this is not something unique to Greenplum Database.

Although you cannot update a sequence directly, you can use a query like:

```
SELECT * FROM sequence_name;
```

to examine the parameters and current state of a sequence. In particular, the *last\_value* field of the sequence shows the last value allocated by any session.

---

## Parameters

### TEMPORARY | TEMP

If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

### *name*

The name (optionally schema-qualified) of the sequence to be created.

### *increment*

Specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.

### *minvalue*

#### NO MINVALUE

Determines the minimum value a sequence can generate. If this clause is not supplied or `NO MINVALUE` is specified, then defaults will be used. The defaults are 1 and -263-1 for ascending and descending sequences, respectively.

### *maxvalue*

#### NO MAXVALUE

Determines the maximum value for the sequence. If this clause is not supplied or `NO MAXVALUE` is specified, then default values will be used. The defaults are 263-1 and -1 for ascending and descending sequences, respectively.

### *start*

Allows the sequence to begin anywhere. The default starting value is *minvalue* for ascending sequences and *maxvalue* for descending ones.

**cache**

Specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The minimum (and default) value is 1 (no cache).

**CYCLE****NO CYCLE**

Allows the sequence to wrap around when the *maxvalue* (for ascending) or *minvalue* (for descending) has been reached. If the limit is reached, the next number generated will be the *minvalue* (for ascending) or *maxvalue* (for descending). If **NO CYCLE** is specified, any calls to *nextval* after the sequence has reached its maximum value will return an error. If not specified, **NO CYCLE** is the default.

**OWNED BY table.column****OWNED BY NONE**

Causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence. **OWNED BY NONE**, the default, specifies that there is no such association.

---

**Notes**

Sequences are based on bigint arithmetic, so the range cannot exceed the range of an eight-byte integer (-9223372036854775808 to 9223372036854775807).

Although multiple sessions are guaranteed to allocate distinct sequence values, the values may be generated out of sequence when all the sessions are considered. For example, session A might reserve values 1..10 and return *nextval*=1, then session B might reserve values 11..20 and return *nextval*=11 before session A has generated *nextval*=2. Thus, you should only assume that the *nextval* values are all distinct, not that they are generated purely sequentially. Also, *last\_value* will reflect the latest value reserved by any session, whether or not it has yet been returned by *nextval*.

---

**Examples**

Create a sequence named *myseq*:

```
CREATE SEQUENCE myseq START 101;
```

Insert a row into a table that gets the next value:

```
INSERT INTO distributors VALUES (nextval('myseq'), 'acme');
```

Reset the sequence counter value on the master:

```
SELECT setval('myseq', 201);
```

Illegal use of *setval* in Greenplum Database (setting sequence values on distributed data):

```
INSERT INTO product VALUES (setval('myseq', 201), 'gizmo');
```

---

## Compatibility

`CREATE SEQUENCE` conforms to the SQL standard, with the following exceptions:

- The `AS data_type` expression specified in the SQL standard is not supported.
- Obtaining the next value is done using the `nextval()` function instead of the `NEXT VALUE FOR` expression specified in the SQL standard.
- The `OWNED BY` clause is a Greenplum Database extension.

---

## Description

**CREATE TABLE** creates an initially empty table in the current database. The user who issues the command owns the table.

If you specify a schema name, Greenplum creates the table in the specified schema. Otherwise Greenplum creates the table in the current schema. Temporary tables exist in a special schema, so you cannot specify a schema name when creating a temporary table. Table names must be distinct from the name of any other table, external table, sequence, index, or view in the same schema.

The optional constraint clauses specify conditions that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways. Constraints apply to tables, not to partitions. You cannot add a constraint to a partition or subpartition.

Referential integrity constraints (foreign keys) are accepted but not enforced. The information is kept in the system catalogs but is otherwise ignored.

There are two ways to define constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column, and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

When creating a table, there is an additional clause to declare the Greenplum Database distribution policy. If a `DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clause is not supplied, then Greenplum assigns a hash distribution policy to the table using either the `PRIMARY KEY` (if the table has one) or the first column of the table as the distribution key. Columns of geometric or user-defined data types are not eligible as Greenplum distribution key columns. If a table does not have a column of an eligible data type, the rows are distributed based on a round-robin or random distribution. To ensure an even distribution of data in your Greenplum Database system, you want to choose a distribution key that is unique for each record, or if that is not possible, then choose `DISTRIBUTED RANDOMLY`.

The `PARTITION BY` clause allows you to divide the table into multiple sub-tables (or parts) that, taken together, make up the parent table and share its schema. Though the sub-tables exist as independent tables, the Greenplum Database restricts their use in important ways. Internally, partitioning is implemented as a special form of inheritance. Each child table partition is created with a distinct `CHECK` constraint which limits the data the table can contain, based on some defining criteria. The `CHECK` constraints are also used by the query planner to determine which table partitions to scan in order to satisfy a given query predicate. These partition constraints are managed automatically by the Greenplum Database.

---

## Parameters

### **GLOBAL | LOCAL**

These keywords are present for SQL standard compatibility, but have no effect in Greenplum Database.

### **TEMPORARY | TEMP**

If specified, the table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see `ON COMMIT`). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

### ***table\_name***

The name (optionally schema-qualified) of the table to be created.

### ***column\_name***

The name of a column to be created in the new table.

***data\_type***

The data type of the column. This may include array specifiers.

**DEFAULT *default\_expr***

The **DEFAULT** clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column. The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

**INHERITS**

The optional **INHERITS** clause specifies a list of tables from which the new table automatically inherits all columns. Use of **INHERITS** creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

In Greenplum Database, the **INHERITS** clause is not used when creating partitioned tables. Although the concept of inheritance is used in partition hierarchies, the inheritance structure of a partitioned table is created using the **PARTITION BY** clause.

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. However, inherited and new column declarations of the same name need not specify identical constraints: all constraints provided from any declaration are merged together and all are applied to the new table. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or an error will be reported.

**LIKE *other\_table* [{**INCLUDING** | **EXCLUDING**} {**DEFAULTS** | **CONSTRAINTS**}]**

The **LIKE** clause specifies a table from which the new table automatically copies all column names, data types, not-null constraints, and distribution policy. Storage properties like append-optimized or partition structure are not copied. Unlike **INHERITS**, the new table and original table are completely decoupled after creation is complete.

Default expressions for the copied column definitions will only be copied if **INCLUDING DEFAULTS** is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having null defaults.

Not-null constraints are always copied to the new table. **CHECK** constraints will only be copied if **INCLUDING CONSTRAINTS** is specified; other types of constraints will *never* be copied. Also, no distinction is made between column constraints and table constraints — when constraints are requested, all check constraints are copied.

Note also that unlike `INHERITS`, copied columns and constraints are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another `LIKE` clause an error is signalled.

#### **CONSTRAINT *constraint\_name***

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like *column must be positive* can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

**Note:** The specified *constraint\_name* is used for the constraint, but a system-generated unique name is used for the index name. In some prior releases, the provided name was used for both the constraint name and the index name.

#### **NULL | NOT NULL**

Specifies if the column is or is not allowed to contain null values. `NULL` is the default.

#### **UNIQUE ( *column constraint* )**

#### **UNIQUE ( *column\_name* [, ... ] ) ( *table constraint* )**

The `UNIQUE` constraint specifies that a group of one or more columns of a table may contain only unique values. The behavior of the unique table constraint is the same as that for column constraints, with the additional capability to span multiple columns. For the purpose of a unique constraint, null values are not considered equal. The column(s) that are unique must contain all the columns of the Greenplum distribution key. In addition, the `<key>` must contain all the columns in the partition key if the table is partitioned. Note that a `<key>` constraint in a partitioned table is not the same as a simple `UNIQUE INDEX`.

#### **PRIMARY KEY ( *column constraint* )**

#### **PRIMARY KEY ( *column\_name* [, ... ] ) ( *table constraint* )**

The primary key constraint specifies that a column or columns of a table may contain only unique (non-duplicate), non-null values. Technically, `PRIMARY KEY` is merely a combination of `UNIQUE` and `NOT NULL`, but identifying a set of columns as primary key also provides metadata about the design of the schema, as a primary key implies that other tables may rely on this set of columns as a unique identifier for rows. For a table to have a primary key, it must be hash distributed (not randomly distributed), and the primary key The column(s) that are unique must contain all the columns of the Greenplum distribution key. In addition, the `<key>` must contain all the columns in the partition key if the table is partitioned. Note that a `<key>` constraint in a partitioned table is not the same as a simple `UNIQUE INDEX`.

#### **CHECK ( *expression* )**

The `CHECK` clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to `TRUE` or `UNKNOWN` succeed. Should any row of an insert or update operation produce a `FALSE` result an error exception is raised and the insert or update does not alter the database. A check constraint specified as a column constraint

should reference that column's value only, while an expression appearing in a table constraint may reference multiple columns. `CHECK` expressions cannot contain subqueries nor refer to variables other than columns of the current row.

```
REFERENCES table_name [ ( column_name [, ... ] ) ]
[ key_match_type ] [ key_action ]

FOREIGN KEY ( column_name [, ... ] )
REFERENCES table_name [ ( column_name [, ... ] ) ]
[ key_match_type ] [ key_action [ key_checking_mode ]
```

The `REFERENCES` and `FOREIGN KEY` clauses specify referential integrity constraints (foreign key constraints). Greenplum accepts referential integrity constraints as specified in PostgreSQL syntax but does not enforce them. See the PostgreSQL documentation for information about referential integrity constraints.

```
WITH ( storage_option=value )
```

The `WITH` clause can be used to set storage options for the table or its indexes. Note that you can also set storage parameters on a particular partition or subpartition by declaring the `WITH` clause in the partition specification.

The following storage options are available:

**APPENDONLY** - Set to `TRUE` to create the table as an append-optimized table. If `FALSE` or not declared, the table will be created as a regular heap-storage table.

**BLOCKSIZE** - Set to the size, in bytes for each block in a table. The `BLOCKSIZE` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

**ORIENTATION** - Set to `column` for column-oriented storage, or `row` (the default) for row-oriented storage. This option is only valid if `APPENDONLY=TRUE`. Heap-storage tables can only be row-oriented.

**COMPRESSTYPE** - Set to `ZLIB` (the default) or `QUICKLZ` to specify the type of compression used. QuickLZ uses less CPU power and compresses data faster at a lower compression ratio than `zlib`. Conversely, `zlib` provides more compact compression ratios at lower speeds. This option is only valid if `APPENDONLY=TRUE`.

**COMPRESSLEVEL** - For `zlib` compression of append-optimized tables, set to a value between 1 (fastest compression) to 9 (highest compression ratio). QuickLZ compression level can only be set to 1. If not declared, the default is 1. This option is only valid if `APPENDONLY=TRUE`.

**FILLFACTOR** - See [CREATE INDEX](#) for more information about this index storage parameter.

**OIDS** - Set to `OIDS=FALSE` (the default) so that rows do not have object identifiers assigned to them. Greenplum strongly recommends that you do not enable OIDS when creating a table. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In

addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. OIDs are not allowed on partitioned tables or append-optimized column-oriented tables.

#### **ON COMMIT**

The behavior of temporary tables at the end of a transaction block can be controlled using **ON COMMIT**. The three options are:

##### **PRESERVE ROWS**

No special action is taken at the ends of transactions for temporary tables. This is the default behavior.

##### **DELETE ROWS**

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic **TRUNCATE** is done at each commit.

##### **DROP**

The temporary table will be dropped at the end of the current transaction block.

#### **TABLESPACE *tablespace***

The name of the tablespace in which the new table is to be created. If not specified, the database's default tablespace is used.

#### **USING INDEX TABLESPACE *tablespace***

This clause allows selection of the tablespace in which the index associated with a **UNIQUE** or **PRIMARY KEY** constraint will be created. If not specified, the database's default tablespace is used.

#### **DISTRIBUTED BY (*column*, [ ... ] ) DISTRIBUTED RANDOMLY**

Used to declare the Greenplum Database distribution policy for the table. **DISTRIBUTED BY** uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose **DISTRIBUTED RANDOMLY**, which will send the data round-robin to the segment instances. If not supplied, then hash distribution is chosen using the **PRIMARY KEY** (if the table has one) or the first eligible column of the table as the distribution key.

#### **PARTITION BY**

Declares one or more columns by which to partition the table.

##### ***partition\_type***

Declares partition type: **LIST** (list of values) or **RANGE** (a numeric or date range).

##### ***partition\_specification***

Declares the individual partitions to create. Each partition can be defined individually or, for range partitions, you can use the **EVERY** clause (with a **START** and optional **END** clause) to define an increment pattern to use to create the individual partitions.

**DEFAULT PARTITION *name*** - Declares a default partition. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition.

**PARTITION *name*** - Declares a name to use for the partition. Partitions are created using the following naming convention:

*parentname\_level#\_prt\_givename.*

**VALUES** - For list partitions, defines the value(s) that the partition will contain.

**START** - For range partitions, defines the starting range value for the partition. By default, start values are **INCLUSIVE**. For example, if you declared a start date of '2008-01-01', then the partition would contain all dates greater than or equal to '2008-01-01'. Typically the data type of the **START** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**END** - For range partitions, defines the ending range value for the partition. By default, end values are **EXCLUSIVE**. For example, if you declared an end date of '2008-02-01', then the partition would contain all dates less than but not equal to '2008-02-01'. Typically the data type of the **END** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**EVERY** - For range partitions, defines how to increment the values from **START** to **END** to create individual partitions. Typically the data type of the **EVERY** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**WITH** - Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables.

**TABLESPACE** - The name of the tablespace in which the partition is to be created.

#### **SUBPARTITION BY**

Declares one or more columns by which to subpartition the first-level partitions of the table. The format of the subpartition specification is similar to that of a partition specification described above.

#### **SUBPARTITION TEMPLATE**

Instead of declaring each subpartition definition individually for each partition, you can optionally declare a subpartition template to be used to create the subpartitions. This subpartition specification would then apply to all parent partitions.

---

## Notes

Using OIDs in new applications is not recommended: where possible, using a `SERIAL` or other sequence generator as the table's primary key is preferred. However, if your application does make use of OIDs to identify specific rows of a table, it is recommended to create a unique constraint on the OID column of that table, to ensure that OIDs in the table will indeed uniquely identify rows even after counter wrap-around. Avoid assuming that OIDs are unique across tables; if you need a database-wide unique identifier, use the combination of table OID and row OID for the purpose.

Greenplum Database has some special conditions for primary key and unique constraints with regards to columns that are the *distribution key* in a Greenplum table. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not `DISTRIBUTED RANDOMLY`), and the constraint columns must be the same as (or a superset of) the table's distribution key columns.

A primary key constraint is simply a combination of a unique constraint and a not-null constraint.

Greenplum Database automatically creates an index for each unique constraint or primary key constraint to enforce uniqueness. Thus, it is not necessary to create an index explicitly for primary key columns.

Foreign key constraints are not supported in Greenplum Database.

For inherited tables, unique constraints, primary key constraints, indexes and table privileges *are not* inherited in the current implementation.

For append-optimized tables, `UPDATE` and `DELETE` are not allowed in a serializable transaction and will cause the transaction to abort. `CLUSTER`, `DECLARE . . . FOR UPDATE`, and triggers are not supported with append-optimized tables.

Execution of `INSERT`, `UPDATE` and `DELETE` commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, these commands must be executed on the root partitioned table, the table created with the `CREATE TABLE` command.

---

## Examples

Create a table named *rank* in the schema named *baby* and distribute the data using the columns *rank*, *gender*, and *year*:

```
CREATE TABLE baby.rank (id int, rank int, year smallint,
gender char(1), count int ) DISTRIBUTED BY (rank, gender,
year);
```

Create table *films* and table *distributors* (the primary key will be used as the Greenplum distribution key by default):

```
CREATE TABLE films (
code          char(5) CONSTRAINT firstkey PRIMARY KEY,
title         varchar(40) NOT NULL,
did           integer NOT NULL,
date_prod     date,
```

```

kind          varchar(10),
len           interval hour to minute
);

```

```

CREATE TABLE distributors (
did          integer PRIMARY KEY DEFAULT nextval('serial'),
name        varchar(40) NOT NULL CHECK (name <> '')
);

```

Create a gzip-compressed, append-optimized table:

```

CREATE TABLE sales (txn_id int, qty int, date date)
WITH (appendonly=true, compresslevel=5)
DISTRIBUTED BY (txn_id);

```

Create a three level partitioned table using subpartition templates and default partitions at each level:

```

CREATE TABLE sales (id int, year int, month int, day int,
region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)

SUBPARTITION BY RANGE (month)
SUBPARTITION TEMPLATE (
START (1) END (13) EVERY (1),
DEFAULT SUBPARTITION other_months )

SUBPARTITION BY LIST (region)
SUBPARTITION TEMPLATE (
SUBPARTITION usa VALUES ('usa'),
SUBPARTITION europe VALUES ('europe'),
SUBPARTITION asia VALUES ('asia'),
DEFAULT SUBPARTITION other_regions)

( START (2002) END (2010) EVERY (1),
DEFAULT PARTITION outlying_years);

```

---

## Compatibility

CREATE TABLE command conforms to the SQL standard, with the following exceptions:

- **Temporary Tables** — In the SQL standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. Greenplum Database instead requires each session to issue its own CREATE TEMPORARY TABLE command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard's approach constrains all instances of a given temporary table name to have the same table structure.

The standard's distinction between global and local temporary tables is not in Greenplum Database. Greenplum Database will accept the GLOBAL and LOCAL keywords in a temporary table declaration, but they have no effect.

If the `ON COMMIT` clause is omitted, the SQL standard specifies that the default behavior is `ON COMMIT DELETE ROWS`. However, the default behavior in Greenplum Database is `ON COMMIT PRESERVE ROWS`. The `ON COMMIT DROP` option does not exist in the SQL standard.

- **Column Check Constraints** — The SQL standard says that `CHECK` column constraints may only refer to the column they apply to; only `CHECK` table constraints may refer to multiple columns. Greenplum Database does not enforce this restriction; it treats column and table check constraints alike.
- **NULL Constraint** — The `NULL` constraint is a Greenplum Database extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the `NOT NULL` constraint). Since it is the default for any column, its presence is not required.
- **Inheritance** — Multiple inheritance via the `INHERITS` clause is a Greenplum Database language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by Greenplum Database.
- **Partitioning** — Table partitioning via the `PARTITION BY` clause is a Greenplum Database language extension.
- **Zero-column tables** — Greenplum Database allows a table of no columns to be created (for example, `CREATE TABLE foo();`). This is an extension from the SQL standard, which does not allow zero-column tables. Zero-column tables are not in themselves very useful, but disallowing them creates odd special cases for `ALTER TABLE DROP COLUMN`, so Greenplum decided to ignore this spec restriction.
- **WITH clause** — The `WITH` clause is a Greenplum Database extension; neither storage parameters nor OIDs are in the standard.
- **Tablespaces** — The Greenplum Database concept of tablespaces is not part of the SQL standard. The clauses `TABLESPACE` and `USING INDEX TABLESPACE` are extensions.
- **Data Distribution** — The Greenplum Database concept of a parallel or distributed database is not part of the SQL standard. The `DISTRIBUTED` clauses are extensions.

---

## CREATE TABLE AS

Defines a new table from the results of a query.

---

### Synopsis

```
CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} ] TABLE table_name
    [(column_name [, ...] )]
    [ WITH ( storage_parameter=value [, ...] ) ]
    [ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP}]
    [TABLESPACE tablespace]
    AS query
    [DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY]
```

where *storage\_parameter* is:

```
APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
COMPRESSTYPE={ZLIB|QUICKLZ}
COMPRESSLEVEL={1-9 | 1}
FILLFACTOR={10-100}
OIDS [=TRUE|FALSE]
```

---

### Description

CREATE TABLE AS creates a table and fills it with data computed by a [SELECT](#) command. The table columns have the names and data types associated with the output columns of the SELECT, however you can override the column names by giving an explicit list of new column names.

CREATE TABLE AS creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query.

---

### Parameters

**GLOBAL | LOCAL**

These keywords are present for SQL standard compatibility, but have no effect in Greenplum Database.

**TEMPORARY | TEMP**

If specified, the new table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see ON COMMIT). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

***table\_name***

The name (optionally schema-qualified) of the new table to be created.

***column\_name***

The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query. If the table is created from an `EXECUTE` command, a column name list cannot be specified.

**WITH ( *storage\_parameter=value* )**

The `WITH` clause can be used to set storage options for the table or its indexes. Note that you can also set different storage parameters on a particular partition or subpartition by declaring the `WITH` clause in the partition specification. The following storage options are available:

**APPENDONLY** - Set to `TRUE` to create the table as an append-optimized table. If `FALSE` or not declared, the table will be created as a regular heap-storage table.

**BLOCKSIZE** - Set to the size, in bytes for each block in a table. The `BLOCKSIZE` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768.

**ORIENTATION** - Set to `column` for column-oriented storage, or `row` (the default) for row-oriented storage. This option is only valid if `APPENDONLY=TRUE`. Heap-storage tables can only be row-oriented.

**COMPRESSTYPE** - Set to `ZLIB` (the default) or `QUICKLZ` to specify the type of compression used. QuickLZ uses less CPU power and compresses data faster at a lower compression ratio than `zlib`. Conversely, `zlib` provides more compact compression ratios at lower speeds. This option is only valid if `APPENDONLY=TRUE`.

**COMPRESSLEVEL** - For `zlib` compression of append-optimized tables, set to a value between 1 (fastest compression) to 9 (highest compression ratio). QuickLZ compression level can only be set to 1. If not declared, the default is 1. This option is only valid if `APPENDONLY=TRUE`.

**FILLFACTOR** - See [CREATE INDEX](#) for more information about this index storage parameter.

**OIDS** - Set to `OIDS=FALSE` (the default) so that rows do not have object identifiers assigned to them. Greenplum strongly recommends that you do not enable OIDS when creating a table. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. OIDs are not allowed on column-oriented tables.

**ON COMMIT**

The behavior of temporary tables at the end of a transaction block can be controlled using `ON COMMIT`. The three options are:

**PRESERVE ROWS**

No special action is taken at the ends of transactions for temporary tables. This is the default behavior.

**DELETE ROWS**

All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic `TRUNCATE` is done at each commit.

**DROP**

The temporary table will be dropped at the end of the current transaction block.

**TABLESPACE *tablespace***

The tablespace is the name of the tablespace in which the new table is to be created. If not specified, the database's default tablespace is used.

**AS *query***

A `SELECT` or `VALUES` command, or an `EXECUTE` command that runs a prepared `SELECT` or `VALUES` query.

**DISTRIBUTED BY (*column*, [ ... ] )  
DISTRIBUTED RANDOMLY**

Used to declare the Greenplum Database distribution policy for the table. One or more columns can be used as the distribution key, meaning those columns are used by the hashing algorithm to divide the data evenly across all of the segments. The distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose to distribute randomly, which will send the data round-robin to the segment instances. If not supplied, then either the `PRIMARY KEY` (if the table has one) or the first eligible column of the table will be used.

---

**Notes**

This command is functionally similar to `SELECT INTO`, but it is preferred since it is less likely to be confused with other uses of the `SELECT INTO` syntax. Furthermore, `CREATE TABLE AS` offers a superset of the functionality offered by `SELECT INTO`.

`CREATE TABLE AS` can be used for fast data loading from external table data sources. See `CREATE EXTERNAL TABLE`.

---

**Examples**

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
CREATE TABLE films_recent AS SELECT * FROM films WHERE
date_prod >= '2007-01-01';
```

Create a new temporary table *films\_recent*, consisting of only recent entries from the table *films*, using a prepared statement. The new table has OIDs and will be dropped at commit:

```
PREPARE recentfilms(date) AS SELECT * FROM films WHERE
date_prod > $1;
CREATE TEMP TABLE films_recent WITH (OIDs) ON COMMIT DROP AS
EXECUTE recentfilms('2007-01-01');
```

---

## Compatibility

`CREATE TABLE AS` conforms to the SQL standard, with the following exceptions:

- The standard requires parentheses around the subquery clause; in Greenplum Database, these parentheses are optional.
- The standard defines a `WITH [NO] DATA` clause; this is not currently implemented by Greenplum Database. The behavior provided by Greenplum Database is equivalent to the standard's `WITH DATA` case. `WITH NO DATA` can be simulated by appending `LIMIT 0` to the query.
- Greenplum Database handles temporary tables differently from the standard; see `CREATE TABLE` for details.
- The `WITH` clause is a Greenplum Database extension; neither storage parameters nor OIDs are in the standard.
- The Greenplum Database concept of tablespaces is not part of the standard. The `TABLESPACE` clause is an extension.

---

## CREATE TABLESPACE

Defines a new tablespace.

---

### Synopsis

```
CREATE TABLESPACE tablespace_name [OWNER username]
      FILESPACE filespace_name
```

---

### Description

CREATE TABLESPACE registers a new tablespace for your Greenplum Database system. The tablespace name must be distinct from the name of any existing tablespace in the system.

A tablespace allows superusers to define an alternative location on the file system where the data files containing database objects (such as tables and indexes) may reside.

A user with appropriate privileges can pass a tablespace name to [CREATE DATABASE](#), [CREATE TABLE](#), or [CREATE INDEX](#) to have the data files for these objects stored within the specified tablespace.

In Greenplum Database, there must be a file system location defined for the master, each primary segment, and each mirror segment in order for the tablespace to have a location to store its objects across an entire Greenplum system. This collection of file system locations is defined in a filespace object. A filespace must be defined before you can create a tablespace. See `gpfilespace` in the *Greenplum Database Utility Guide* for more information.

---

### Parameters

#### ***tablespacename***

The name of a tablespace to be created. The name cannot begin with `pg_` or `gp_`, as such names are reserved for system tablespaces.

#### **OWNER *username***

The name of the user who will own the tablespace. If omitted, defaults to the user executing the command. Only superusers may create tablespaces, but they can assign ownership of tablespaces to non-superusers.

#### **FILESPACE**

The name of a Greenplum Database filespace that was defined using the `CREATE FILESPACE` command or the `gpfilespace` management utility.

---

### Notes

You must first create a filespace to be used by the tablespace. See `gpfilespace` in the *Greenplum Database Utility Guide* for more information.

Tablespaces are only supported on systems that support symbolic links.

`CREATE TABLESPACE` cannot be executed inside a transaction block.

---

## Examples

Create a new tablespace by specifying the corresponding filespace to use:

```
CREATE TABLESPACE mytblspace FILESPACE myfilespace;
```

---

## Compatibility

`CREATE TABLESPACE` is a Greenplum Database extension.

---

---

## CREATE TRIGGER

Defines a new trigger. User-defined triggers are not supported in Greenplum Database.

---

### Synopsis

```
CREATE TRIGGER name {BEFORE | AFTER} {event [OR ...]}
  ON table [ FOR [EACH] {ROW | STATEMENT} ]
  EXECUTE PROCEDURE funcname ( arguments )
```

---

### Description

CREATE TRIGGER creates a new trigger. The trigger will be associated with the specified table and will execute the specified function when certain events occur.

Due to the distributed nature of a Greenplum Database system, the use of triggers is very limited in Greenplum Database. The function used in the trigger must be IMMUTABLE, meaning it cannot use information not directly present in its argument list. The function specified in the trigger also cannot execute any SQL or modify distributed database objects in any way. Given that triggers are most often used to alter tables (for example, update these other rows when this row is updated), these limitations offer very little practical use of triggers in Greenplum Database. For that reason, Greenplum does not support the use of user-defined triggers in Greenplum Database. Triggers cannot be used on append-optimized tables.

If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.

SELECT does not modify any rows so you can not create SELECT triggers. Rules and views are more appropriate in such cases.

---

### Parameters

#### *name*

The name to give the new trigger. This must be distinct from the name of any other trigger for the same table.

#### BEFORE AFTER

Determines whether the function is called before or after the event. If the trigger fires before the event, the trigger may skip the operation for the current row, or change the row being inserted (for INSERT and UPDATE operations only). If the trigger fires after the event, all changes, including the last insertion, update, or deletion, are visible to the trigger.

#### *event*

Specifies the event that will fire the trigger (INSERT, UPDATE, or DELETE). Multiple events can be specified using OR.

***table***

The name (optionally schema-qualified) of the table the trigger is for.

**FOR EACH ROW  
FOR EACH STATEMENT**

This specifies whether the trigger procedure should be fired once for every row affected by the trigger event, or just once per SQL statement. If neither is specified, `FOR EACH STATEMENT` is the default. A trigger that is marked `FOR EACH ROW` is called once for every row that the operation modifies. In contrast, a trigger that is marked `FOR EACH STATEMENT` only executes once for any given operation, regardless of how many rows it modifies.

***funcname***

A user-supplied function that is declared as `IMMUTABLE`, taking no arguments, and returning type `trigger`, which is executed when the trigger fires. This function must not execute SQL or modify the database in any way.

***arguments***

An optional comma-separated list of arguments to be provided to the function when the trigger is executed. The arguments are literal string constants. Simple names and numeric constants may be written here, too, but they will all be converted to strings. Please check the description of the implementation language of the trigger function about how the trigger arguments are accessible within the function; it may be different from normal function arguments.

---

**Notes**

To create a trigger on a table, the user must have the `TRIGGER` privilege on the table.

---

**Examples**

Declare the trigger function and then a trigger:

```
CREATE FUNCTION sendmail() RETURNS trigger AS
'$GPHOME/lib/emailtrig.so' LANGUAGE C IMMUTABLE;

CREATE TRIGGER t_sendmail AFTER INSERT OR UPDATE OR DELETE
ON mytable FOR EACH STATEMENT EXECUTE PROCEDURE sendmail();
```

---

**Compatibility**

The `CREATE TRIGGER` statement in Greenplum Database implements a subset of the SQL standard. The following functionality is currently missing:

- Greenplum Database has strict limitations on the function that is called by a trigger, which makes the use of triggers very limited in Greenplum Database. For this reason, triggers are not officially supported in Greenplum Database.
- SQL allows triggers to fire on updates to specific columns (e.g., `AFTER UPDATE OF col1, col2`).

- SQL allows you to define aliases for the ‘old’ and ‘new’ rows or tables for use in the definition of the triggered action (e.g., `CREATE TRIGGER ... ON tablename REFERENCING OLD ROW AS somename NEW ROW AS othername ...`). Since Greenplum Database allows trigger procedures to be written in any number of user-defined languages, access to the data is handled in a language-specific way.
- Greenplum Database only allows the execution of a user-defined function for the triggered action. The standard allows the execution of a number of other SQL commands, such as `CREATE TABLE` as the triggered action. This limitation is not hard to work around by creating a user-defined function that executes the desired commands.
- SQL specifies that multiple triggers should be fired in time-of-creation order. Greenplum Database uses name order, which was judged to be more convenient.
- SQL specifies that `BEFORE DELETE` triggers on cascaded deletes fire after the cascaded `DELETE` completes. The Greenplum Database behavior is for `BEFORE DELETE` to always fire before the delete action, even a cascading one. This is considered more consistent.
- The ability to specify multiple actions for a single trigger using `OR` is a Greenplum Database extension of the SQL standard.

---

## CREATE TYPE

Defines a new data type.

---

### Synopsis

```
CREATE TYPE name AS ( attribute_name data_type [, ... ] )

CREATE TYPE name (
    INPUT = input_function,
    OUTPUT = output_function
    [, RECEIVE = receive_function]
    [, SEND = send_function]
    [, INTERNALLENGTH = {internallength | VARIABLE}]
    [, PASSEDBYVALUE]
    [, ALIGNMENT = alignment]
    [, STORAGE = storage]
    [, DEFAULT = default]
    [, ELEMENT = element]
    [, DELIMITER = delimiter]
)

CREATE TYPE name
```

---

### Description

`CREATE TYPE` registers a new data type for use in the current database. The user who defines a type becomes its owner.

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. The type name must also be distinct from the name of any existing table in the same schema.

### Composite Types

The first form of `CREATE TYPE` creates a composite type. The composite type is specified by a list of attribute names and data types. This is essentially the same as the row type of a table, but using `CREATE TYPE` avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful as the argument or return type of a function.

### Base Types

The second form of `CREATE TYPE` creates a new base type (scalar type). The parameters may appear in any order, not only that shown in the syntax, and most are optional. You must register two or more functions (using `CREATE FUNCTION`) before defining the type. The support functions *input\_function* and *output\_function* are required, while the functions *receive\_function*, *send\_function* and *analyze\_function* are optional. Generally these functions have to be coded in C or another low-level language. In Greenplum Database, any function used to implement a data type must be defined as `IMMUTABLE`.

The *input\_function* converts the type's external textual representation to the internal representation used by the operators and functions defined for the type. *output\_function* performs the reverse transformation. The input function may be declared as taking one argument of type *cstring*, or as taking three arguments of types *cstring*, *oid*, *integer*. The first argument is the input text as a C string, the second argument is the type's own OID (except for array types, which instead receive their element type's OID), and the third is the *typmod* of the destination column, if known (-1 will be passed if not). The input function must return a value of the data type itself. Usually, an input function should be declared *STRICT*; if it is not, it will be called with a *NULL* first parameter when reading a *NULL* input value. The function must still return *NULL* in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which may need to reject *NULL* inputs.) The output function must be declared as taking one argument of the new data type. The output function must return type *cstring*. Output functions are not invoked for *NULL* values.

The optional *receive\_function* converts the type's external binary representation to the internal representation. If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid. The receive function may be declared as taking one argument of type *internal*, or as taking three arguments of types *internal*, *oid*, *integer*. The first argument is a pointer to a *StringInfo* buffer holding the received byte string; the optional arguments are the same as for the text input function. The receive function must return a value of the data type itself. Usually, a receive function should be declared *STRICT*; if it is not, it will be called with a *NULL* first parameter when reading a *NULL* input value. The function must still return *NULL* in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which may need to reject *NULL* inputs.) Similarly, the optional *send\_function* converts from the internal representation to the external binary representation. If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one argument of the new data type. The send function must return type *bytea*. Send functions are not invoked for *NULL* values.

You should at this point be wondering how the input and output functions can be declared to have results or arguments of the new type, when they have to be created before the new type can be created. The answer is that the type should first be defined as a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the I/O functions can be defined referencing the shell type. Finally, `CREATE TYPE` with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to Greenplum Database. Foremost of these is *internallength*. Base data types can be fixed-length, in which case *internallength* is a positive integer, or variable length, indicated by setting

*internallength* to `VARIABLE`. (Internally, this is represented by setting `typelen` to `-1`.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type.

The optional flag `PASSEDBYVALUE` indicates that values of this data type are passed by value, rather than by reference. You may not pass by value types whose internal representation is larger than the size of the `Datum` type (4 bytes on most machines, 8 bytes on a few).

The *alignment* parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an `int4` as their first component.

The *storage* parameter allows selection of storage strategies for variable-length data types. (Only `plain` is allowed for fixed-length types.) `plain` specifies that data of the type will always be stored in-line and not compressed. `extended` specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it's still too long. `external` allows the value to be moved out of the main table, but the system will not try to compress it. `main` allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy may still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over `extended` and `external` items.)

A default value may be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the `DEFAULT` key word. (Such a default may be overridden by an explicit `DEFAULT` clause attached to a particular column.)

To indicate that a type is an array, specify the type of the array elements using the `ELEMENT` key word. For example, to define an array of 4-byte integers (`int4`), specify `ELEMENT = int4`. More details about array types appear below.

To indicate the delimiter to be used between values in the external representation of arrays of this type, *delimiter* can be set to a specific character. The default delimiter is the comma (`,`). Note that the delimiter is associated with the array element type, not the array type itself.

## Array Types

Whenever a user-defined base data type is created, Greenplum Database automatically creates an associated array type, whose name consists of the base type's name prepended with an underscore. The parser understands this naming convention, and translates requests for columns of type `foo[]` into requests for type `_foo`. The implicitly-created array type is variable length and uses the built-in input and output functions `array_in` and `array_out`.

You might reasonably ask why there is an `ELEMENT` option, if the system makes the correct array type automatically. The only case where it's useful to use `ELEMENT` is when you are making a fixed-length type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you plan to provide for the type as a whole. For example, type `name` allows its constituent `char` elements to be accessed

this way. A 2-D point type could allow its two component numbers to be accessed like `point[0]` and `point[1]`. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. A subscriptable variable-length type must have the generalized internal representation used by `array_in` and `array_out`. For historical reasons, subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

---

## Parameters

### ***name***

The name (optionally schema-qualified) of a type to be created.

### ***attribute\_name***

The name of an attribute (column) for the composite type.

### ***data\_type***

The name of an existing data type to become a column of the composite type.

### ***input\_function***

The name of a function that converts data from the type's external textual form to its internal form.

### ***output\_function***

The name of a function that converts data from the type's internal form to its external textual form.

### ***receive\_function***

The name of a function that converts data from the type's external binary form to its internal form.

### ***send\_function***

The name of a function that converts data from the type's internal form to its external binary form.

### ***internallength***

A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

### ***alignment***

The storage alignment requirement of the data type. Must be one of `char`, `int2`, `int4`, or `double`. The default is `int4`.

### ***storage***

The storage strategy for the data type. Must be one of `plain`, `external`, `extended`, or `main`. The default is `plain`.

***default***

The default value for the data type. If this is omitted, the default is null.

***element***

The type being created is an array; this specifies the type of the array elements.

***delimiter***

The delimiter character to be used between values in arrays made of this type.

---

**Notes**

User-defined type names cannot begin with the underscore character (`_`) and can only be 62 characters long (or in general `NAMEDATALEN - 2`, rather than the `NAMEDATALEN - 1` characters allowed for other names). Type names beginning with underscore are reserved for internally-created array type names.

Because there are no restrictions on use of a data type once it's been created, creating a base type is tantamount to granting public execute permission on the functions mentioned in the type definition. (The creator of the type is therefore required to own these functions.) This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require 'secret' information to be used while converting it to or from external form.

Before Greenplum Database version 2.4, the syntax `CREATE TYPE name` did not exist. The way to create a new base type was to create its input function first. In this approach, Greenplum Database will first see the name of the new data type as the return type of the input function. The shell type is implicitly created in this situation, and then it can be referenced in the definitions of the remaining I/O functions. This approach still works, but is deprecated and may be disallowed in some future release. Also, to avoid accidentally cluttering the catalogs with shell types as a result of simple typos in function definitions, a shell type will only be made this way when the input function is written in C.

---

**Examples**

This example creates a composite type and uses it in a function definition:

```
CREATE TYPE compfoo AS (f1 int, f2 text);

CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
    SELECT fooid, foename FROM foo
$$ LANGUAGE SQL;
```

This example creates the base data type *box* and then uses the type in a table definition:

```
CREATE TYPE box;

CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS
... ;
```

```
CREATE FUNCTION my_box_out_function(box) RETURNScstring AS
... ;
```

```
CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function
);
```

```
CREATE TABLE myboxes (
    id integer,
    description box
);
```

If the internal structure of *box* were an array of four float4 elements, we might instead use:

```
CREATE TYPE box (
    INTERNALLENGTH = 16,
    INPUT = my_box_in_function,
    OUTPUT = my_box_out_function,
    ELEMENT = float4
);
```

which would allow a box value's component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

```
CREATE TYPE bigobj (
    INPUT = lo_filein, OUTPUT = lo_fileout,
    INTERNALLENGTH = VARIABLE
);

CREATE TABLE big_objs (
    id integer,
    obj bigobj
);
```

---

## Compatibility

This `CREATE TYPE` command is a Greenplum Database extension. There is a `CREATE TYPE` statement in the SQL standard that is rather different in detail.

---

## See Also

[CREATE FUNCTION](#), [ALTER TYPE](#), [DROP TYPE](#), [CREATE DOMAIN](#)

---

## CREATE USER

Defines a new database role with the LOGIN privilege by default.

---

### Synopsis

```
CREATE USER name [ [WITH] option [ ... ] ]
```

where *option* can be:

```

SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'
| VALID UNTIL 'timestamp'
| IN ROLE rolename [, ...]
| IN GROUP rolename [, ...]
| ROLE rolename [, ...]
| ADMIN rolename [, ...]
| USER rolename [, ...]
| SYSID uid
| RESOURCE QUEUE queue_name
```

---

### Description

As of Greenplum Database release 2.2, CREATE USER has been replaced by [CREATE ROLE](#), although it is still accepted for backwards compatibility.

The only difference between CREATE ROLE and CREATE USER is that LOGIN is assumed by default with CREATE USER, whereas NOLOGIN is assumed by default with CREATE ROLE.

---

### Compatibility

There is no CREATE USER statement in the SQL standard.

---

### See Also

[CREATE ROLE](#)

---

## CREATE VIEW

Defines a new view.

---

### Synopsis

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] VIEW name
    [ ( column_name [, ...] ) ]
    AS query
```

---

### Description

CREATE VIEW defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

CREATE OR REPLACE VIEW is similar, but if a view of the same name already exists, it is replaced. You can only replace a view with a new query that generates the identical set of columns (same column names and data types).

If a schema name is given then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so a schema name may not be given when creating a temporary view. The name of the view must be distinct from the name of any other view, table, sequence, or index in the same schema.

---

### Parameters

#### TEMPORARY | TEMP

If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names. If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether TEMPORARY is specified or not).

#### *name*

The name (optionally schema-qualified) of a view to be created.

#### *column\_name*

An optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

#### *query*

A [SELECT](#) or [VALUES](#) command which will provide the columns and rows of the view.

---

## Notes

Views in Greenplum Database are read only. The system will not allow an insert, update, or delete on a view. You can get the effect of an updatable view by creating rewrite rules on the view into appropriate actions on other tables. For more information see `CREATE RULE`.

Be careful that the names and data types of the view's columns will be assigned the way you want. For example:

```
CREATE VIEW vista AS SELECT 'Hello World';
```

is bad form in two ways: the column name defaults to `?column?`, and the column data type defaults to `unknown`. If you want a string literal in a view's result, use something like:

```
CREATE VIEW vista AS SELECT text 'Hello World' AS hello;
```

Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser). This can be confusing in the case of superusers, since superusers typically have access to all objects. In the case of a view, even superusers must be explicitly granted access to tables referenced in the view if they are not the owner of the view.

However, functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore the user of a view must have permissions to call any functions used by the view.

If you create a view with an `ORDER BY` clause, the `ORDER BY` clause is ignored when you do a `SELECT` from the view.

---

## Examples

Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS SELECT * FROM films WHERE kind =
'comedy';
```

Create a view that gets the top ten ranked baby names:

```
CREATE VIEW topten AS SELECT name, rank, gender, year FROM
names, rank WHERE rank < '11' AND names.id=rank.id;
```

---

## Compatibility

The SQL standard specifies some additional capabilities for the `CREATE VIEW` statement that are not in Greenplum Database. The optional clauses for the full SQL command in the standard are:

- **CHECK OPTION** — This option has to do with updatable views. All `INSERT` and `UPDATE` commands on the view will be checked to ensure data satisfy the view-defining condition (that is, the new data would be visible through the view). If they do not, the update will be rejected.
- **LOCAL** — Check for integrity on this view.

- **CASCADED** — Check for integrity on this view and on any dependent view. CASCADED is assumed if neither CASCADED nor LOCAL is specified.

CREATE OR REPLACE VIEW is a Greenplum Database language extension. So is the concept of a temporary view.

---

## See Also

[SELECT](#), [DROP VIEW](#)

---

## DEALLOCATE

Deallocates a prepared statement.

---

### Synopsis

```
DEALLOCATE [PREPARE] name
```

---

### Description

DEALLOCATE is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see [PREPARE](#).

---

### Parameters

#### PREPARE

Optional key word which is ignored.

#### *name*

The name of the prepared statement to deallocate.

---

### Examples

Deallocated the previously prepared statement named *insert\_names*:

```
DEALLOCATE insert_names;
```

---

### Compatibility

The SQL standard includes a DEALLOCATE statement, but it is only for use in embedded SQL.

---

### See Also

[EXECUTE](#), [PREPARE](#)

---

## DECLARE

Defines a cursor.

---

### Synopsis

```
DECLARE name [BINARY] [INSENSITIVE] [NO SCROLL] CURSOR
        [{WITH | WITHOUT} HOLD]
        FOR query [FOR READ ONLY]
```

---

### Description

DECLARE allows a user to create cursors, which can be used to retrieve a small number of rows at a time out of a larger query. Cursors can return data either in text or in binary format using [FETCH](#).

Normal cursors return data in text format, the same as a SELECT would produce. Since data is stored natively in binary format, the system must do a conversion to produce the text format. Once the information comes back in text form, the client application may need to convert it to a binary format to manipulate it. In addition, data in the text format is often larger in size than in the binary format. Binary cursors return the data in a binary representation that may be more easily manipulated. Nevertheless, if you intend to display the data as text anyway, retrieving it in text form will save you some effort on the client side.

As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including psql, are not prepared to handle binary cursors and expect data to come back in the text format.

**Note:** When the client application uses the ‘extended query’ protocol to issue a [FETCH](#) command, the Bind protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

A cursor can be specified in the WHERE CURRENT OF clause of the [UPDATE](#) or [DELETE](#) command to update or delete table data.

---

### Parameters

#### *name*

The name of the cursor to be created.

#### **BINARY**

Causes the cursor to return data in binary rather than in text format.

**INSENSITIVE**

Indicates that data retrieved from the cursor should be unaffected by updates to the tables underlying the cursor while the cursor exists. In Greenplum Database, all cursors are insensitive. This key word currently has no effect and is present for compatibility with the SQL standard.

**NO SCROLL**

A cursor cannot be used to retrieve rows in a nonsequential fashion. This is the default behavior in Greenplum Database, since scrollable cursors (**SCROLL**) are not supported.

**WITH HOLD  
WITHOUT HOLD**

**WITH HOLD** specifies that the cursor may continue to be used after the transaction that created it successfully commits. **WITHOUT HOLD** specifies that the cursor cannot be used outside of the transaction that created it. **WITHOUT HOLD** is the default.

**WITH HOLD** cannot not be specified when the *query* includes a **FOR UPDATE** or **FOR SHARE** clause.

***query***

A **SELECT** or **VALUES** command which will provide the rows to be returned by the cursor.

If the cursor is used in the **WHERE CURRENT OF** clause of the **UPDATE** or **DELETE** command, the **SELECT** command must satisfy the following conditions:

- Cannot reference a view or external table.
- References only one table.  
The table must be updatable. For example, the following are not updatable: table functions, set-returning functions, append-only tables, columnar tables.
- Cannot contain any of the following:
  - A grouping clause
  - A set operation such as **UNION ALL** or **UNION DISTINCT**
  - A sorting clause
  - A windowing clause
  - A join or a self-join

Specifying the **FOR UPDATE** clause in the **SELECT** command prevents other sessions from changing the rows between the time they are fetched and the time they are updated. Without the **FOR UPDATE** clause, a subsequent use of the **UPDATE** or **DELETE** command with the **WHERE CURRENT OF** clause has no effect if the row was changed since the cursor was created.

**Important:** Specifying the **FOR UPDATE** clause in the **SELECT** command locks the entire table, not just the selected rows.

**FOR READ ONLY**

**FOR READ ONLY** indicates that the cursor is used in a read-only mode.

---

## Notes

Unless `WITH HOLD` is specified, the cursor created by this command can only be used within the current transaction. Thus, `DECLARE` without `WITH HOLD` is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore Greenplum Database reports an error if this command is used outside a transaction block. Use `BEGIN`, `COMMIT` and `ROLLBACK` to define a transaction block.

If `WITH HOLD` is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction is aborted, the cursor is removed.) A cursor created with `WITH HOLD` is closed when an explicit `CLOSE` command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

Scrollable cursors are not currently supported in Greenplum Database. You can only use `FETCH` to move the cursor position forward, not backwards.

`DECLARE . . . FOR UPDATE` is not supported with append-optimized tables.

You can see all available cursors by querying the `pg_cursors` system view.

---

## Examples

Declare a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM mytable;
```

---

## Compatibility

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

Greenplum Database does not implement an `OPEN` statement for cursors. A cursor is considered to be open when it is declared.

The SQL standard allows cursors to move both forward and backward. All Greenplum Database cursors are forward moving only (not scrollable).

Binary cursors are a Greenplum Database extension.

---

## See Also

[CLOSE](#), [DELETE](#), [FETCH](#), [MOVE](#), [SELECT](#), [UPDATE](#)

## DELETE

Deletes rows from a table.

### Synopsis

```
DELETE FROM [ONLY] table [[AS] alias]
    [USING usinglist]
    [WHERE condition | WHERE CURRENT OF cursor_name ]
```

### Description

DELETE deletes rows that satisfy the WHERE clause from the specified table. If the WHERE clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

By default, DELETE will delete rows in the specified table and all its child tables. If you wish to delete only from the specific table mentioned, you must use the ONLY clause.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the USING clause. Which technique is more appropriate depends on the specific circumstances.

If the WHERE CURRENT OF clause is specified, the row that is deleted is the one most recently fetched from the specified cursor.

You must have the DELETE privilege on the table to delete from it.

### Outputs

On successful completion, a DELETE command returns a command tag of the form

```
DELETE count
```

The count is the number of rows deleted. If count is 0, no rows matched the condition (this is not considered an error).

### Parameters

#### ONLY

If specified, delete rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

#### *table*

The name (optionally schema-qualified) of an existing table.

#### *alias*

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given DELETE FROM foo AS f, the remainder of the DELETE statement must refer to this table as f not foo.

***usinglist***

A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition. This is similar to the list of tables that can be specified in the `FROM` Clause of a `SELECT` statement; for example, an alias for the table name can be specified. Do not repeat the target table in the `usinglist`, unless you wish to set up a self-join.

***condition***

An expression returning a value of type `boolean`, which determines the rows that are to be deleted.

***cursor\_name***

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a simple (non-join, non-aggregate) query on the `DELETE` target table. See [DECLARE](#) for more information about creating cursors.

`WHERE CURRENT OF` cannot be specified together with a Boolean condition.

See [DECLARE](#) for more information about creating cursors.

---

**Notes**

Greenplum Database lets you reference columns of other tables in the `WHERE` condition by specifying the other tables in the `USING` clause. For example, to the name *Hannah* from the *rank* table, one might do:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND
name = 'Hannah';
```

What is essentially happening here is a join between *rank* and *names*, with all successfully joined rows being marked for deletion. This syntax is not standard. However, this join style is usually easier to write and faster to execute than a more standard sub-select style, such as:

```
DELETE FROM rank WHERE id IN (SELECT id FROM names WHERE name
= 'Hannah');
```

When using `DELETE` to remove all the rows of a table (for example: `DELETE * FROM table;`), Greenplum Database adds an implicit `TRUNCATE` command (when user permissions allow). The added `TRUNCATE` command frees the disk space occupied by the deleted rows without requiring a `VACUUM` of the table. This improves scan performance of subsequent queries, and benefits ELT workloads that frequently insert and delete from temporary tables.

Execution of `INSERT`, `UPDATE` and `DELETE` commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, these commands must be executed on the root partitioned table, the table created with the `CREATE TABLE` command.

---

**Examples**

Delete all films but musicals:

```
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table films:

```
DELETE FROM films;
```

Delete using a join:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND  
name = 'Hannah';
```

---

## Compatibility

This command conforms to the SQL standard, except that the `USING` clause is a Greenplum Database extension.

---

## See Also

[DECLARE](#), [TRUNCATE](#)

---

## DROP AGGREGATE

Removes an aggregate function.

---

### Synopsis

```
DROP AGGREGATE [IF EXISTS] name ( type [, ...] ) [CASCADE |  
RESTRICT]
```

---

### Description

DROP AGGREGATE will delete an existing aggregate function. To execute this command the current user must be the owner of the aggregate function.

---

### Parameters

#### IF EXISTS

Do not throw an error if the aggregate does not exist. A notice is issued in this case.

#### *name*

The name (optionally schema-qualified) of an existing aggregate function.

#### *type*

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write \* in place of the list of input data types.

#### CASCADE

Automatically drop objects that depend on the aggregate function.

#### RESTRICT

Refuse to drop the aggregate function if any objects depend on it. This is the default.

---

### Examples

To remove the aggregate function *myavg* for type *integer*:

```
DROP AGGREGATE myavg(integer);
```

---

### Compatibility

There is no DROP AGGREGATE statement in the SQL standard.

---

### See Also

[ALTER AGGREGATE](#), [CREATE AGGREGATE](#)

---

## DROP CAST

Removes a cast.

---

### Synopsis

```
DROP CAST [IF EXISTS] (sourcetype AS targettype) [CASCADE |  
RESTRICT]
```

---

### Description

`DROP CAST` will delete a previously defined cast. To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the cast does not exist. A notice is issued in this case.

#### ***sourcetype***

The name of the source data type of the cast.

#### ***targettype***

The name of the target data type of the cast.

#### **CASCADE**

#### **RESTRICT**

These keywords have no effect since there are no dependencies on casts.

---

### Examples

To drop the cast from type *text* to type *int*:

```
DROP CAST (text AS int);
```

---

### Compatibility

There `DROP CAST` command conforms to the SQL standard.

---

### See Also

[CREATE CAST](#)

---

## DROP CONVERSION

Removes a conversion.

---

### Synopsis

```
DROP CONVERSION [IF EXISTS] name [CASCADE | RESTRICT]
```

---

### Description

`DROP CONVERSION` removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the conversion does not exist. A notice is issued in this case.

#### ***name***

The name of the conversion. The conversion name may be schema-qualified.

#### **CASCADE**

#### **RESTRICT**

These keywords have no effect since there are no dependencies on conversions.

---

### Examples

Drop the conversion named *myname*:

```
DROP CONVERSION myname;
```

---

### Compatibility

There is no `DROP CONVERSION` statement in the SQL standard.

---

### See Also

[ALTER CONVERSION](#), [CREATE CONVERSION](#)

---

## DROP DATABASE

Removes a database.

---

### Synopsis

```
DROP DATABASE [IF EXISTS] name
```

---

### Description

`DROP DATABASE` drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be executed by the database owner. Also, it cannot be executed while you or anyone else are connected to the target database. (Connect to *template1* or any other database to issue this command.)

`DROP DATABASE` cannot be undone. Use it with care!

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the database does not exist. A notice is issued in this case.

#### ***name***

The name of the database to remove.

---

### Notes

`DROP DATABASE` cannot be executed inside a transaction block.

This command cannot be executed while connected to the target database. Thus, it might be more convenient to use the program `dropdb` instead, which is a wrapper around this command.

---

### Examples

Drop the database named *testdb*:

```
DROP DATABASE testdb;
```

---

### Compatibility

There is no `DROP DATABASE` statement in the SQL standard.

---

### See Also

[ALTER DATABASE](#), [CREATE DATABASE](#)

---

## DROP DOMAIN

Removes a domain.

---

### Synopsis

```
DROP DOMAIN [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP DOMAIN` removes a previously defined domain. You must be the owner of a domain to drop it.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the domain does not exist. A notice is issued in this case.

#### ***name***

The name (optionally schema-qualified) of an existing domain.

#### **CASCADE**

Automatically drop objects that depend on the domain (such as table columns).

#### **RESTRICT**

Refuse to drop the domain if any objects depend on it. This is the default.

---

### Examples

Drop the domain named *zipcode*:

```
DROP DOMAIN zipcode;
```

---

### Compatibility

This command conforms to the SQL standard, except for the `IF EXISTS` option, which is a Greenplum Database extension.

---

### See Also

[ALTER DOMAIN](#), [CREATE DOMAIN](#)

---

## DROP EXTERNAL TABLE

Removes an external table definition.

---

### Synopsis

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] name [CASCADE | RESTRICT]
```

---

### Description

`DROP EXTERNAL TABLE` drops an existing external table definition from the database system. The external data sources or files are not deleted. To execute this command you must be the owner of the external table.

---

### Parameters

#### WEB

Optional keyword for dropping external web tables.

#### IF EXISTS

Do not throw an error if the external table does not exist. A notice is issued in this case.

#### *name*

The name (optionally schema-qualified) of an existing external table.

#### CASCADE

Automatically drop objects that depend on the external table (such as views).

#### RESTRICT

Refuse to drop the external table if any objects depend on it. This is the default.

---

### Examples

Remove the external table named *staging* if it exists:

```
DROP EXTERNAL TABLE IF EXISTS staging;
```

---

### Compatibility

There is no `DROP EXTERNAL TABLE` statement in the SQL standard.

---

### See Also

[CREATE EXTERNAL TABLE](#)

---

## DROP FILESPACE

Removes a filespace.

---

### Synopsis

```
DROP FILESPACE [IF EXISTS] filespacename
```

---

### Description

DROP FILESPACE removes a filespace definition and its system-generated data directories from the system.

A filespace can only be dropped by its owner or a superuser. The filespace must be empty of all tablespace objects before it can be dropped. It is possible that tablespaces in other databases may still be using a filespace even if no tablespaces in the current database are using the filespace.

---

### Parameters

#### IF EXISTS

Do not throw an error if the filespace does not exist. A notice is issued in this case.

#### *tablespace*name

The name of the filespace to remove.

---

### Examples

Remove the tablespace *myfs*:

```
DROP FILESPACE myfs;
```

---

### Compatibility

There is no DROP FILESPACE statement in the SQL standard or in PostgreSQL.

---

### See Also

[ALTER FILESPACE](#), `gpfilespace` in the *Greenplum Database Utility Guide*, [DROP TABLESPACE](#)

---

## DROP FUNCTION

Removes a function.

---

### Synopsis

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype
[, ...] ] ) [CASCADE | RESTRICT]
```

---

### Description

`DROP FUNCTION` removes the definition of an existing function. To execute this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions may exist with the same name and different argument lists.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the function does not exist. A notice is issued in this case.

#### ***name***

The name (optionally schema-qualified) of an existing function.

#### ***argmode***

The mode of an argument: either `IN`, `OUT`, or `INOUT`. If omitted, the default is `IN`.

Note that `DROP FUNCTION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN` and `INOUT` arguments.

#### ***argname***

The name of an argument. Note that `DROP FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

#### ***argtype***

The data type(s) of the function's arguments (optionally schema-qualified), if any.

#### **CASCADE**

Automatically drop objects that depend on the function (such as operators or triggers).

#### **RESTRICT**

Refuse to drop the function if any objects depend on it. This is the default.

---

## Examples

Drop the square root function:

```
DROP FUNCTION sqrt(integer);
```

---

## Compatibility

A `DROP FUNCTION` statement is defined in the SQL standard, but it is not compatible with this command.

---

## See Also

[CREATE FUNCTION](#), [ALTER FUNCTION](#)

---

## DROP GROUP

Removes a database role.

---

### Synopsis

```
DROP GROUP [IF EXISTS] name [, ...]
```

---

### Description

`DROP GROUP` is an obsolete command, though still accepted for backwards compatibility. Groups (and users) have been superseded by the more general concept of roles. See [DROP ROLE](#) for more information.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the role does not exist. A notice is issued in this case.

#### ***name***

The name of an existing role.

---

### Compatibility

There is no `DROP GROUP` statement in the SQL standard.

---

### See Also

[DROP ROLE](#)

---

## DROP INDEX

Removes an index.

---

### Synopsis

```
DROP INDEX [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP INDEX` drops an existing index from the database system. To execute this command you must be the owner of the index.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the index does not exist. A notice is issued in this case.

#### ***name***

The name (optionally schema-qualified) of an existing index.

#### **CASCADE**

Automatically drop objects that depend on the index.

#### **RESTRICT**

Refuse to drop the index if any objects depend on it. This is the default.

---

### Examples

Remove the index *title\_idx*:

```
DROP INDEX title_idx;
```

---

### Compatibility

`DROP INDEX` is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.

---

### See Also

[ALTER INDEX](#), [CREATE INDEX](#), [REINDEX](#)

---

## DROP LANGUAGE

Removes a procedural language.

---

### Synopsis

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] name [CASCADE | RESTRICT]
```

---

### Description

`DROP LANGUAGE` will remove the definition of the previously registered procedural language. You must be a superuser to drop a language.

---

### Parameters

#### **PROCEDURAL**

Optional keyword - has no effect.

#### **IF EXISTS**

Do not throw an error if the language does not exist. A notice is issued in this case.

#### ***name***

The name of an existing procedural language. For backward compatibility, the name may be enclosed by single quotes.

#### **CASCADE**

Automatically drop objects that depend on the language (such as functions written in that language).

#### **RESTRICT**

Refuse to drop the language if any objects depend on it. This is the default.

---

### Examples

Remove the procedural language *plsample*:

```
DROP LANGUAGE plsample;
```

---

### Compatibility

There is no `DROP LANGUAGE` statement in the SQL standard.

---

### See Also

[ALTER LANGUAGE](#), [CREATE LANGUAGE](#)

---

## DROP OPERATOR

Removes an operator.

---

### Synopsis

```
DROP OPERATOR [IF EXISTS] name ( {lefttype | NONE} , {righttype
| NONE} ) [CASCADE | RESTRICT]
```

---

### Description

DROP OPERATOR drops an existing operator from the database system. To execute this command you must be the owner of the operator.

---

### Parameters

#### IF EXISTS

Do not throw an error if the operator does not exist. A notice is issued in this case.

#### *name*

The name (optionally schema-qualified) of an existing operator.

#### *lefttype*

The data type of the operator's left operand; write NONE if the operator has no left operand.

#### *righttype*

The data type of the operator's right operand; write NONE if the operator has no right operand.

#### CASCADE

Automatically drop objects that depend on the operator.

#### RESTRICT

Refuse to drop the operator if any objects depend on it. This is the default.

---

### Examples

Remove the power operator  $a^b$  for type *integer*:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the left unary bitwise complement operator  $\sim b$  for type *bit*:

```
DROP OPERATOR ~ (none, bit);
```

Remove the right unary factorial operator  $x!$  for type *bigint*:

```
DROP OPERATOR ! (bigint, none);
```

---

**Compatibility**

There is no `DROP OPERATOR` statement in the SQL standard.

---

**See Also**

[ALTER OPERATOR](#), [CREATE OPERATOR](#)

---

## DROP OPERATOR CLASS

Removes an operator class.

---

### Synopsis

```
DROP OPERATOR CLASS [IF EXISTS] name USING index_method [CASCADE  
| RESTRICT]
```

---

### Description

DROP OPERATOR drops an existing operator class. To execute this command you must be the owner of the operator class.

---

### Parameters

#### IF EXISTS

Do not throw an error if the operator class does not exist. A notice is issued in this case.

#### *name*

The name (optionally schema-qualified) of an existing operator class.

#### *index\_method*

The name of the index access method the operator class is for.

#### CASCADE

Automatically drop objects that depend on the operator class.

#### RESTRICT

Refuse to drop the operator class if any objects depend on it. This is the default.

---

### Examples

Remove the B-tree operator class *widget\_ops*:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add CASCADE to drop such indexes along with the operator class.

---

### Compatibility

There is no DROP OPERATOR CLASS statement in the SQL standard.

---

### See Also

[ALTER OPERATOR CLASS](#), [CREATE OPERATOR CLASS](#)

---

## DROP OWNED

Removes database objects owned by a database role.

---

### Synopsis

```
DROP OWNED BY name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP OWNED` drops all the objects in the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database will also be revoked.

---

### Parameters

#### *name*

The name of a role whose objects will be dropped, and whose privileges will be revoked.

#### **CASCADE**

Automatically drop objects that depend on the affected objects.

#### **RESTRICT**

Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

---

### Notes

`DROP OWNED` is often used to prepare for the removal of one or more roles. Because `DROP OWNED` only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

Using the `CASCADE` option may make the command recurse to objects owned by other users.

The `REASSIGN OWNED` command is an alternative that reassigns the ownership of all the database objects owned by one or more roles.

---

### Examples

Remove any database objects owned by the role named *sally*:

```
DROP OWNED BY sally;
```

---

### Compatibility

The `DROP OWNED` statement is a Greenplum Database extension.

---

## See Also

[REASSIGN OWNED](#), [DROP ROLE](#)

---

## DROP RESOURCE QUEUE

Removes a resource queue.

---

### Synopsis

```
DROP RESOURCE QUEUE queue_name
```

---

### Description

This command removes a workload management resource queue from Greenplum Database. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. Only a superuser can drop a resource queue.

---

### Parameters

*queue\_name*

The name of a resource queue to remove.

---

### Notes

Use [ALTER ROLE](#) to remove a user from a resource queue.

To see all the currently active queries for all resource queues, perform the following query of the `pg_locks` table joined with the `pg_roles` and `pg_resqueue` tables:

```
SELECT rolname, rsqname, locktype, objid, transaction, pid,
       mode, granted FROM pg_roles, pg_resqueue, pg_locks WHERE
       pg_roles.rolresqueue=pg_locks.objid AND
       pg_locks.objid=pg_resqueue.oid;
```

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and `pg_resqueue` system catalog tables:

```
SELECT rolname, rsqname FROM pg_roles, pg_resqueue WHERE
       pg_roles.rolresqueue=pg_resqueue.oid;
```

---

### Examples

Remove a role from a resource queue (and move the role to the default resource queue, `pg_default`):

```
ALTER ROLE bob RESOURCE QUEUE NONE;
```

Remove the resource queue named *adhoc*:

```
DROP RESOURCE QUEUE adhoc;
```

---

### Compatibility

The `DROP RESOURCE QUEUE` statement is a Greenplum Database extension.

---

**See Also**

[ALTER RESOURCE QUEUE](#), [CREATE RESOURCE QUEUE](#), [ALTER ROLE](#)

---

## DROP ROLE

Removes a database role.

---

### Synopsis

```
DROP ROLE [IF EXISTS] name [, ...]
```

---

### Description

`DROP ROLE` removes the specified role(s). To drop a superuser role, you must be a superuser yourself. To drop non-superuser roles, you must have `CREATEROLE` privilege.

A role cannot be removed if it is still referenced in any database; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted. The `REASSIGN OWNED` and `DROP OWNED` commands can be useful for this purpose.

However, it is not necessary to remove role memberships involving the role; `DROP ROLE` automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the role does not exist. A notice is issued in this case.

#### ***name***

The name of the role to remove.

---

### Examples

Remove the roles named *sally* and *bob*:

```
DROP ROLE sally, bob;
```

---

### Compatibility

The SQL standard defines `DROP ROLE`, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than Greenplum Database uses.

---

### See Also

[REASSIGN OWNED](#), [DROP OWNED](#), [CREATE ROLE](#), [ALTER ROLE](#), [SET ROLE](#)

---

## DROP RULE

Removes a rewrite rule.

---

### Synopsis

```
DROP RULE [IF EXISTS] name ON relation [CASCADE | RESTRICT]
```

---

### Description

`DROP RULE` drops a rewrite rule from a table or view.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the rule does not exist. A notice is issued in this case.

#### ***name***

The name of the rule to remove.

#### ***relation***

The name (optionally schema-qualified) of the table or view that the rule applies to.

#### **CASCADE**

Automatically drop objects that depend on the rule.

#### **RESTRICT**

Refuse to drop the rule if any objects depend on it. This is the default.

---

### Examples

Remove the rewrite rule *sales\_2006* on the table *sales*:

```
DROP RULE sales_2006 ON sales;
```

---

### Compatibility

There is no `DROP RULE` statement in the SQL standard.

---

### See Also

[CREATE RULE](#)

---

## DROP TYPE

Removes a data type.

---

### Synopsis

```
DROP TYPE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP TYPE` will remove a user-defined data type. Only the owner of a type can remove it.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the type does not exist. A notice is issued in this case.

#### ***name***

The name (optionally schema-qualified) of the data type to remove.

#### **CASCADE**

Automatically drop objects that depend on the type (such as table columns, functions, operators).

#### **RESTRICT**

Refuse to drop the type if any objects depend on it. This is the default.

---

### Examples

Remove the data type *box*;

```
DROP TYPE box;
```

---

### Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a Greenplum Database extension. But note that the `CREATE TYPE` command and the data type extension mechanisms in Greenplum Database differ from the SQL standard.

---

### See Also

[ALTER TYPE](#), [CREATE TYPE](#)

---

## DROP SCHEMA

Removes a schema.

---

### Synopsis

```
DROP SCHEMA [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP SCHEMA` removes schemas from the database. A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if he does not own some of the objects within the schema.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the schema does not exist. A notice is issued in this case.

#### ***name***

The name of the schema to remove.

#### **CASCADE**

Automatically drops any objects contained in the schema (tables, functions, etc.).

#### **RESTRICT**

Refuse to drop the schema if it contains any objects. This is the default.

---

### Examples

Remove the schema *mystuff* from the database, along with everything it contains:

```
DROP SCHEMA mystuff CASCADE;
```

---

### Compatibility

`DROP SCHEMA` is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

---

### See Also

[CREATE SCHEMA](#), [ALTER SCHEMA](#)

---

## DROP SEQUENCE

Removes a sequence.

---

### Synopsis

```
DROP SEQUENCE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP SEQUENCE` removes a sequence generator table. You must own the sequence to drop it (or be a superuser).

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the sequence does not exist. A notice is issued in this case.

#### ***name***

The name (optionally schema-qualified) of the sequence to remove.

#### **CASCADE**

Automatically drop objects that depend on the sequence.

#### **RESTRICT**

Refuse to drop the sequence if any objects depend on it. This is the default.

---

### Examples

Remove the sequence *myserial*:

```
DROP SEQUENCE myserial;
```

---

### Compatibility

`DROP SEQUENCE` is fully conforming with the SQL standard, except that the standard only allows one sequence to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

---

### See Also

[ALTER SEQUENCE](#), [CREATE SEQUENCE](#)

---

## DROP TABLE

Removes a table.

---

### Synopsis

```
DROP TABLE [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP TABLE` removes tables from the database. Only its owner may drop a table. To empty a table of rows without removing the table definition, use `DELETE` or `TRUNCATE`.

`DROP TABLE` always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view, `CASCADE` must be specified. `CASCADE` will remove a dependent view entirely.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the table does not exist. A notice is issued in this case.

#### ***name***

The name (optionally schema-qualified) of the table to remove.

#### **CASCADE**

Automatically drop objects that depend on the table (such as views).

#### **RESTRICT**

Refuse to drop the table if any objects depend on it. This is the default.

---

### Examples

Remove the table *mytable*:

```
DROP TABLE mytable;
```

---

### Compatibility

`DROP TABLE` is fully conforming with the SQL standard, except that the standard only allows one table to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

---

### See Also

[CREATE TABLE](#), [ALTER TABLE](#), [TRUNCATE](#)

---

## DROP TABLESPACE

Removes a tablespace.

---

### Synopsis

```
DROP TABLESPACE [IF EXISTS] tablespacename
```

---

### Description

DROP TABLESPACE removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases may still reside in the tablespace even if no objects in the current database are using the tablespace.

---

### Parameters

#### IF EXISTS

Do not throw an error if the tablespace does not exist. A notice is issued in this case.

#### *tablespacename*

The name of the tablespace to remove.

---

### Examples

Remove the tablespace *mystuff*:

```
DROP TABLESPACE mystuff;
```

---

### Compatibility

DROP TABLESPACE is a Greenplum Database extension.

---

### See Also

[CREATE TABLESPACE](#), [ALTER TABLESPACE](#)

---

## DROP TRIGGER

Removes a trigger.

---

### Synopsis

```
DROP TRIGGER [IF EXISTS] name ON table [CASCADE | RESTRICT]
```

---

### Description

DROP TRIGGER will remove an existing trigger definition. To execute this command, the current user must be the owner of the table for which the trigger is defined.

---

### Parameters

#### IF EXISTS

Do not throw an error if the trigger does not exist. A notice is issued in this case.

#### *name*

The name of the trigger to remove.

#### *table*

The name (optionally schema-qualified) of the table for which the trigger is defined.

#### CASCADE

Automatically drop objects that depend on the trigger.

#### RESTRICT

Refuse to drop the trigger if any objects depend on it. This is the default.

---

### Examples

Remove the trigger *sendmail* on table *expenses*;

```
DROP TRIGGER sendmail ON expenses;
```

---

### Compatibility

The DROP TRIGGER statement in Greenplum Database is not compatible with the SQL standard. In the SQL standard, trigger names are not local to tables, so the command is simply DROP TRIGGER *name*.

---

### See Also

[ALTER TRIGGER](#), [CREATE TRIGGER](#)

---

## DROP USER

Removes a database role.

---

### Synopsis

```
DROP USER [IF EXISTS] name [, ...]
```

---

### Description

`DROP USER` is an obsolete command, though still accepted for backwards compatibility. Groups (and users) have been superseded by the more general concept of roles. See [DROP ROLE](#) for more information.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the role does not exist. A notice is issued in this case.

#### ***name***

The name of an existing role.

---

### Compatibility

There is no `DROP USER` statement in the SQL standard. The SQL standard leaves the definition of users to the implementation.

---

### See Also

[DROP ROLE](#)

---

## DROP VIEW

Removes a view.

---

### Synopsis

```
DROP VIEW [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

`DROP VIEW` will remove an existing view. Only the owner of a view can remove it.

---

### Parameters

#### **IF EXISTS**

Do not throw an error if the view does not exist. A notice is issued in this case.

#### ***name***

The name (optionally schema-qualified) of the view to remove.

#### **CASCADE**

Automatically drop objects that depend on the view (such as other views).

#### **RESTRICT**

Refuse to drop the view if any objects depend on it. This is the default.

---

### Examples

Remove the view *topten*;

```
DROP VIEW topten;
```

---

### Compatibility

`DROP VIEW` is fully conforming with the SQL standard, except that the standard only allows one view to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

---

### See Also

[CREATE VIEW](#)

---

## END

Commits the current transaction.

---

### Synopsis

```
END [WORK | TRANSACTION]
```

---

### Description

END commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a Greenplum Database extension that is equivalent to [COMMIT](#).

---

### Parameters

**WORK**  
**TRANSACTION**

Optional keywords. They have no effect.

---

### Examples

Commit the current transaction:

```
END;
```

---

### Compatibility

END is a Greenplum Database extension that provides functionality equivalent to [COMMIT](#), which is specified in the SQL standard.

---

### See Also

[BEGIN](#), [ROLLBACK](#), [COMMIT](#)

---

## EXECUTE

Executes a prepared SQL statement.

---

### Synopsis

```
EXECUTE name [ (parameter [, ...] ) ]
```

---

### Description

EXECUTE is used to execute a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a PREPARE statement executed earlier in the current session.

If the PREPARE statement that created the statement specified some parameters, a compatible set of parameters must be passed to the EXECUTE statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see PREPARE.

---

### Parameters

#### *name*

The name of the prepared statement to execute.

#### *parameter*

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

---

### Examples

Create a prepared statement for an INSERT statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO
foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

---

### Compatibility

The SQL standard includes an EXECUTE statement, but it is only for use in embedded SQL. This version of the EXECUTE statement also uses a somewhat different syntax.

---

### See Also

[DEALLOCATE](#), [PREPARE](#)

---

## EXPLAIN

Shows the query plan of a statement.

---

### Synopsis

```
EXPLAIN [ANALYZE] [VERBOSE] statement
```

---

### Description

**EXPLAIN** displays the query plan that the Greenplum planner generates for the supplied statement. Query plans are a tree plan of nodes. Each node in the plan represents a single operation, such as table scan, join, aggregation or a sort.

Plans should be read from the bottom up as each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations (sequential, index or bitmap index scans). If the query requires joins, aggregations, or sorts (or other operations on the raw rows) then there will be additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually the Greenplum Database motion nodes (redistribute, explicit redistribute, broadcast, or gather motions). These are the operations responsible for moving rows between the segment instances during query processing.

The output of **EXPLAIN** has one line for each node in the plan tree, showing the basic node type plus the following cost estimates that the planner made for the execution of that plan node:

- **cost** - measured in units of disk page fetches; that is, 1.0 equals one sequential disk page read. The first estimate is the start-up cost (cost of getting to the first row) and the second is the total cost (cost of getting all rows). Note that the total cost assumes that all rows will be retrieved, which may not always be the case (if using **LIMIT** for example).
- **rows** - the total number of rows output by this plan node. This is usually less than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any **WHERE** clause conditions. Ideally the top-level nodes estimate will approximate the number of rows actually returned, updated, or deleted by the query.
- **width** - total bytes of all the rows output by this plan node.

It is important to note that the cost of an upper-level node includes the cost of all its child nodes. The topmost node of the plan has the estimated total execution cost for the plan. This is this number that the planner seeks to minimize. It is also important to realize that the cost only reflects things that the query planner cares about. In particular, the cost does not consider the time spent transmitting result rows to the client.

**EXPLAIN ANALYZE** causes the statement to be actually executed, not only planned. The **EXPLAIN ANALYZE** plan shows the actual results along with the planner's estimates. This is useful for seeing whether the planner's estimates are close to reality. In addition to the information shown in the **EXPLAIN** plan, **EXPLAIN ANALYZE** will show the following additional information:

- The total elapsed time (in milliseconds) that it took to run the query.
- The number of *workers* (segments) involved in a plan node operation. Only segments that return rows are counted.
- The maximum number of rows returned by the segment that produced the most rows for an operation. If multiple segments produce an equal number of rows, the one with the longest *time to end* is the one chosen.
- The segment id number of the segment that produced the most rows for an operation.
- For relevant operations, the *work\_mem* used by the operation. If *work\_mem* was not sufficient to perform the operation in memory, the plan will show how much data was spilled to disk and how many passes over the data were required for the lowest performing segment. For example:  

```
Work_mem used: 64K bytes avg, 64K bytes max (seg0).
Work_mem wanted: 90K bytes avg, 90K bytes max (seg0) to abate workfile
I/O affecting 2 workers.
[seg0] pass 0: 488 groups made from 488 rows; 263 rows written to
workfile
[seg0] pass 1: 263 groups made from 263 rows
```
- The time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment. The *<time> to first row* may be omitted if it is the same as the *<time> to end*.

**Important:** Keep in mind that the statement is actually executed when EXPLAIN ANALYZE is used. Although EXPLAIN ANALYZE will discard any output that a SELECT would return, other side effects of the statement will happen as usual. If you wish to use EXPLAIN ANALYZE on a DML statement without letting the command affect your data, use this approach:

```
BEGIN;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

---

## Parameters

### *name*

The name of the prepared statement to execute.

### *parameter*

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

---

## Notes

In order to allow the query planner to make reasonably informed decisions when optimizing queries, the ANALYZE statement should be run to record statistics about the distribution of data within the table. If you have not done this (or if the statistical

distribution of the data in the table has changed significantly since the last time `ANALYZE` was run), the estimated costs are unlikely to conform to the real properties of the query, and consequently an inferior query plan may be chosen.

For more information about query profiling, see the *Greenplum Database Database Administrator Guide*.

---

## Examples

To illustrate how to read an `EXPLAIN` query plan, consider the following example for a very simple query:

```
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';
               QUERY PLAN
-----
Gather Motion 2:1 (slice1) (cost=0.00..20.88 rows=1 width=13)
  -> Seq Scan on 'names' (cost=0.00..20.88 rows=1 width=13)
        Filter: name::text ~~ 'Joelle'::text
```

If we read the plan from the bottom up, the query planner starts by doing a sequential scan of the *names* table. Notice that the `WHERE` clause is being applied as a *filter* condition. This means that the scan operation checks the condition for each row it scans, and outputs only the ones that pass the condition.

The results of the scan operation are passed up to a *gather motion* operation. In Greenplum Database, a gather motion is when segments send rows up to the master. In this case we have 2 segment instances sending to 1 master instance (2:1). This operation is working on *slice1* of the parallel query execution plan. In Greenplum Database a query plan is divided into *slices* so that portions of the query plan can be worked on in parallel by the segments.

The estimated startup cost for this plan is 00.00 (no cost) and a total cost of 20.88 disk page fetches. The planner is estimating that this query will return one row.

---

## Compatibility

There is no `EXPLAIN` statement defined in the SQL standard.

---

## See Also

[ANALYZE](#)

## FETCH

Retrieves rows from a query using a cursor.

---

### Synopsis

```
FETCH [ forward_direction { FROM | IN } ] cursorname
```

*where forward\_direction can be empty or one of:*

```
NEXT
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
```

---

### Description

FETCH retrieves rows using a previously-created cursor.

A cursor has an associated position, which is used by FETCH. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If FETCH runs off the end of the available rows then the cursor is left positioned after the last row. FETCH ALL will always leave the cursor positioned after the last row.

The forms NEXT, FIRST, LAST, ABSOLUTE, RELATIVE fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using FORWARD retrieve the indicated number of rows moving in the forward direction, leaving the cursor positioned on the last-returned row (or after all rows, if the count exceeds the number of rows available). Note that it is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using FETCH.

RELATIVE 0 and FORWARD 0 request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row, in which case no row is returned.

### Outputs

On successful completion, a FETCH command returns a command tag of the form

```
FETCH count
```

The count is the number of rows fetched (possibly zero). Note that in `psql`, the command tag will not actually be displayed, since `psql` displays the fetched rows instead.

---

## Parameters

### *forward\_direction*

Defines the fetch direction and number of rows to fetch. Only forward fetches are allowed in Greenplum Database. It can be one of the following:

#### **NEXT**

Fetch the next row. This is the default if direction is omitted.

#### **FIRST**

Fetch the first row of the query (same as `ABSOLUTE 1`). Only allowed if it is the first `FETCH` operation using this cursor.

#### **LAST**

Fetch the last row of the query (same as `ABSOLUTE -1`).

#### **ABSOLUTE count**

Fetch the specified row of the query. Position after last row if count is out of range. Only allowed if the row specified by *count* moves the cursor position forward.

#### **RELATIVE count**

Fetch the specified row of the query *count* rows ahead of the current cursor position. `RELATIVE 0` re-fetches the current row, if any. Only allowed if *count* moves the cursor position forward.

#### **count**

Fetch the next *count* number of rows (same as `FORWARD count`).

#### **ALL**

Fetch all remaining rows (same as `FORWARD ALL`).

#### **FORWARD**

Fetch the next row (same as `NEXT`).

#### **FORWARD count**

Fetch the next *count* number of rows. `FORWARD 0` re-fetches the current row.

#### **FORWARD ALL**

Fetch all remaining rows.

#### **cursorname**

The name of an open cursor.

---

## Notes

Greenplum Database does not support scrollable cursors, so you can only use `FETCH` to move the cursor position forward.

`ABSOLUTE` fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway.

Updating data via a cursor is currently not supported by Greenplum Database.

`DECLARE` is used to define a cursor. Use `MOVE` to change cursor position without retrieving data.

---

## Examples

-- Start the transaction:

```
BEGIN;
```

-- Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

-- Fetch the first 5 rows in the cursor *mycursor*:

```
FETCH FORWARD 5 FROM mycursor;
```

code	title	did	date_prod	kind	len
BL101	The Third Man	101	1949-12-23	Drama	01:44
BL102	The African Queen	101	1951-08-11	Romantic	01:43
JL201	Une Femme est une Femme	102	1961-03-12	Romantic	01:25
P_301	Vertigo	103	1958-11-14	Action	02:08
P_302	Becket	103	1964-02-03	Drama	02:28

-- Close the cursor and end the transaction:

```
CLOSE mycursor;
```

```
COMMIT;
```

---

## Compatibility

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

The variant of `FETCH` described here returns the data as if it were a `SELECT` result rather than placing it in host variables. Other than this point, `FETCH` is fully upward-compatible with the SQL standard.

The `FETCH` forms involving `FORWARD`, as well as the forms `FETCH count` and `FETCH ALL`, in which `FORWARD` is implicit, are Greenplum Database extensions. `BACKWARD` is not supported.

The SQL standard allows only `FROM` preceding the cursor name; the option to use `IN` is an extension.

---

GRANT parent_role [, ...]
    TO member_role [, ...] [WITH ADMIN OPTION]

GRANT { SELECT | INSERT | ALL [PRIVILEGES] }
    ON PROTOCOL protocolname
    TO username
```

---

### Description

The GRANT command has two basic variants: one that grants privileges on a database object (table, view, sequence, database, function, procedural language, schema, or tablespace), and one that grants membership in a role.

#### GRANT on Database Objects

This variant of the GRANT command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

The key word `PUBLIC` indicates that the privileges are to be granted to all roles, including those that may be created later. `PUBLIC` may be thought of as an implicitly defined group-level role that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to `PUBLIC`.

If `WITH GRANT OPTION` is specified, the recipient of the privilege may in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to `PUBLIC`.

There is no need to grant privileges to the owner of an object (usually the role that created it), as the owner has all privileges by default. The right to drop an object, or to alter its definition in any way is not described by a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. The owner implicitly has all grant options for the object, too.

Depending on the type of object, the initial default privileges may include granting some privileges to `PUBLIC`. The default is no public access for tables, schemas, and tablespaces; `CONNECT` privilege and `TEMP` table creation privilege for databases; `EXECUTE` privilege for functions; and `USAGE` privilege for languages. The object owner may of course revoke these privileges.

### Grant on Roles

This variant of the `GRANT` command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.

If `WITH ADMIN OPTION` is specified, the member may in turn grant membership in the role to others, and revoke membership in the role as well. Database superusers can grant or revoke membership in any role to anyone. Roles having `CREATEROLE` privilege can grant or revoke membership in any role that is not a superuser.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`.

### Grant on Protocols

After creating a custom protocol, specify `CREATE TRUSTED PROTOCOL` to be able to allowing any user besides the owner to access it. If the protocol is not trusted, you cannot give any other user permission to use it to read or write data. After a `TRUSTED` protocol is created, you can specify which other users can access it with the `GRANT` command.

- To allow a user to create a readable external table with a trusted protocol  
`GRANT SELECT ON PROTOCOL protocolname TO username`
- To allow a user to create a writable external table with a trusted protocol  
`GRANT INSERT ON PROTOCOL protocolname TO username`
- To allow a user to create both readable and writable external table with a trusted protocol  
`GRANT ALL ON PROTOCOL protocolname TO username`

---

## Parameters

### SELECT

Allows SELECT from any column of the specified table, view, or sequence. Also allows the use of COPY TO. For sequences, this privilege also allows the use of the curval function.

### INSERT

Allows INSERT of a new row into the specified table. Also allows COPY FROM.

### UPDATE

Allows UPDATE of any column of the specified table. SELECT ... FOR UPDATE and SELECT ... FOR SHARE also require this privilege (as well as the SELECT privilege). For sequences, this privilege allows the use of the nextval and setval functions.

### DELETE

Allows DELETE of a row from the specified table.

### REFERENCES

This keyword is accepted, although foreign key constraints are currently not supported in Greenplum Database. To create a foreign key constraint, it is necessary to have this privilege on both the referencing and referenced tables.

### TRIGGER

Allows the creation of a trigger on the specified table.

### CREATE

For databases, allows new schemas to be created within the database.

For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object and have this privilege for the containing schema.

For tablespaces, allows tables and indexes to be created within the tablespace, and allows databases to be created that have the tablespace as their default tablespace. (Note that revoking this privilege will not alter the placement of existing objects.)

### CONNECT

Allows the user to connect to the specified database. This privilege is checked at connection startup (in addition to checking any restrictions imposed by pg\_hba.conf).

### TEMPORARY TEMP

Allows temporary tables to be created while using the database.

**EXECUTE**

Allows the use of the specified function and the use of any operators that are implemented on top of the function. This is the only type of privilege that is applicable to functions. (This syntax works for aggregate functions, as well.)

**USAGE**

For procedural languages, allows the use of the specified language for the creation of functions in that language. This is the only type of privilege that is applicable to procedural languages.

For schemas, allows access to objects contained in the specified schema (assuming that the objects' own privilege requirements are also met). Essentially this allows the grantee to look up objects within the schema.

For sequences, this privilege allows the use of the `currval` and `nextval` functions.

**ALL PRIVILEGES**

Grant all of the available privileges at once. The `PRIVILEGES` key word is optional in Greenplum Database, though it is required by strict SQL.

**PUBLIC**

A special group-level role that denotes that the privileges are to be granted to all roles, including those that may be created later.

**WITH GRANT OPTION**

The recipient of the privilege may in turn grant it to others.

**WITH ADMIN OPTION**

The member of a role may in turn grant membership in the role to others.

---

**Notes**

Database superusers can access all objects regardless of object privilege settings. One exception to this rule is view objects. Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser).

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. For role membership, the membership appears to have been granted by the containing role itself.

`GRANT` and `REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges `WITH GRANT OPTION`.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to `SERIAL` columns. Permissions on a sequence must be set separately.

Greenplum Database does not support granting or revoking privileges for individual columns of a table. One possible workaround is to create a view having just the desired columns and then grant privileges to that view.

Use `psql`'s `\z` meta-command to obtain information about existing privileges for an object.

---

## Examples

Grant insert privilege to all roles on table *mytable*:

```
GRANT INSERT ON mytable TO PUBLIC;
```

Grant all available privileges to role *sally* on the view *topten*. Note that while the above will indeed grant all privileges if executed by a superuser or the owner of *topten*, when executed by someone else it will only grant those permissions for which the granting role has grant options.

```
GRANT ALL PRIVILEGES ON topten TO sally;
```

Grant membership in role *admins* to user *joe*:

```
GRANT admins TO joe;
```

---

## Compatibility

The `PRIVILEGES` key word in is required in the SQL standard, but optional in Greenplum Database. The SQL standard does not support setting the privileges on more than one object per command.

Greenplum Database allows an object owner to revoke his own ordinary privileges: for example, a table owner can make the table read-only to himself by revoking his own `INSERT`, `UPDATE`, and `DELETE` privileges. This is not possible according to the SQL standard. Greenplum Database treats the owner's privileges as having been granted by the owner to himself; therefore he can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed *system* entity.

The SQL standard allows setting privileges for individual columns within a table.

The SQL standard provides for a `USAGE` privilege on other kinds of objects: character sets, collations, translations, domains.

Privileges on databases, tablespaces, schemas, and languages are Greenplum Database extensions.

[REVOKE](#)

---

## INSERT

Creates new rows in a table.

---

### Synopsis

```
INSERT INTO table [( column [, ...] )]
    {DEFAULT VALUES | VALUES ( {expression | DEFAULT} [, ...] )
    [, ...] | query}
```

---

### Description

INSERT inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names may be listed in any order. If no list of column names is given at all, the default is the columns of the table in their declared order. The values supplied by the VALUES clause or query are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is no default.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

You must have INSERT privilege on a table in order to insert into it.

### Outputs

On successful completion, an INSERT command returns a command tag of the form:

```
INSERT oid count
```

The *count* is the number of rows inserted. If count is exactly one, and the target table has OIDs, then *oid* is the OID assigned to the inserted row. Otherwise *oid* is zero.

---

### Parameters

#### *table*

The name (optionally schema-qualified) of an existing table.

#### *column*

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.)

#### DEFAULT VALUES

All columns will be filled with their default values.

#### *expression*

An expression or value to assign to the corresponding column.

**DEFAULT**

The corresponding column will be filled with its default value.

**query**

A query (`SELECT` statement) that supplies the rows to be inserted. Refer to the `SELECT` statement for a description of the syntax.

---

**Notes**

Execution of `INSERT`, `UPDATE` and `DELETE` commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, these commands must be executed on the root partitioned table, the table created with the `CREATE TABLE` command.

---

**Examples**

Insert a single row into table *films*:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105,
    '1971-07-13', 'Comedy', '82 minutes');
```

In this example, the *length* column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
    ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the `DEFAULT` clause for the *date\_prod* column rather than specifying a value:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105, DEFAULT,
    'Comedy', '82 minutes');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the multirow `VALUES` syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
    ('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
    ('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table *films* from a table *tmp\_films* with the same column layout as *films*:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod <
    '2004-05-07';
```

---

**Compatibility**

`INSERT` conforms to the SQL standard. The case in which a column name list is omitted, but not all the columns are filled from the `VALUES` clause or query, is disallowed by the standard.

Possible limitations of the *query* clause are documented under `SELECT`.

---

## See Also

[COPY](#), [SELECT](#), [CREATE EXTERNAL TABLE](#)

---

## LOAD

Loads or reloads a shared library file.

---

### Synopsis

```
LOAD 'filename'
```

---

### Description

This command loads a shared library file into the Greenplum Database server address space. If the file had been loaded previously, it is first unloaded. This command is primarily useful to unload and reload a shared library file that has been changed since the server first loaded it. To make use of the shared library, function(s) in it need to be declared using the `CREATE FUNCTION` command.

The file name is specified in the same way as for shared library names in `CREATE FUNCTION`; in particular, one may rely on a search path and automatic addition of the system's standard shared library file name extension.

Note that in Greenplum Database the shared library file (`.so` file) must reside in the same path location on every host in the Greenplum Database array (masters, segments, and mirrors).

Only database superusers can load shared library files.

---

### Parameters

#### *filename*

The path and file name of a shared library file. This file must exist in the same location on all hosts in your Greenplum Database array.

---

### Examples

Load a shared library file:

```
LOAD '/usr/local/greenplum-db/lib/myfuncs.so';
```

---

### Compatibility

`LOAD` is a Greenplum Database extension.

---

### See Also

[CREATE FUNCTION](#)

## LOCK

Locks a table.

---

### Synopsis

```
LOCK [TABLE] name [, ...] [IN lockmode MODE] [NOWAIT]
```

where *lockmode* is one of:

```
ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE  
EXCLUSIVE | SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS  
EXCLUSIVE
```

---

### Description

`LOCK TABLE` obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If `NOWAIT` is specified, `LOCK TABLE` does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is aborted and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. There is no `UNLOCK TABLE` command; locks are always released at transaction end.

When acquiring locks automatically for commands that reference tables, Greenplum Database always uses the least restrictive lock mode possible. `LOCK TABLE` provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the *Read Committed* isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain `SHARE` lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because `SHARE` lock mode conflicts with the `ROW EXCLUSIVE` lock acquired by writers, and your `LOCK TABLE name IN SHARE MODE` statement will wait until any concurrent holders of `ROW EXCLUSIVE` mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the *Serializable* isolation level, you have to execute the `LOCK TABLE` statement before executing any `SELECT` or data modification statement. A serializable transaction's view of data will be frozen when its first `SELECT` or data modification statement begins. A `LOCK TABLE` later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use `SHARE ROW EXCLUSIVE` lock mode instead of `SHARE` mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire `SHARE` mode, and then be unable to also acquire `ROW EXCLUSIVE` mode to actually perform their updates. Note that a transaction's own locks never conflict, so a transaction can acquire `ROW EXCLUSIVE` mode when it holds `SHARE` mode — but not if anyone else holds `SHARE` mode. To avoid deadlocks, make

sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

---

## Parameters

### *name*

The name (optionally schema-qualified) of an existing table to lock.

If multiple tables are given, tables are locked one-by-one in the order specified in the `LOCK TABLE` command.

### *lockmode*

The lock mode specifies which locks this lock conflicts with. If no lock mode is specified, then `ACCESS EXCLUSIVE`, the most restrictive mode, is used. Lock modes are as follows:

- **ACCESS SHARE** — Conflicts with the **ACCESS EXCLUSIVE** lock mode only. The commands `SELECT` and `ANALYZE` automatically acquire a lock of this mode on referenced tables. In general, any query that only reads a table and does not modify it will acquire this lock mode.
- **ROW SHARE** — Conflicts with the `EXCLUSIVE` and `ACCESS EXCLUSIVE` lock modes. The `SELECT FOR UPDATE` and `SELECT FOR SHARE` commands automatically acquire a lock of this mode on the target table(s) (in addition to `ACCESS SHARE` locks on any other tables that are referenced but not selected `FOR UPDATE/FOR SHARE`).
- **ROW EXCLUSIVE** — Conflicts with the `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. The commands `INSERT` and `COPY` automatically acquire this lock mode on the target table (in addition to `ACCESS SHARE` locks on any other referenced tables).
- **SHARE UPDATE EXCLUSIVE** — Conflicts with the `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode protects a table against concurrent schema changes and `VACUUM` runs. Acquired automatically by `VACUUM` (without `FULL`).
- **SHARE** — Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode protects a table against concurrent data changes. Acquired automatically by `CREATE INDEX`.
- **SHARE ROW EXCLUSIVE** — Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This lock mode is not automatically acquired by any Greenplum Database command.

- **EXCLUSIVE** — Conflicts with the ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE lock modes. This mode allows only concurrent ACCESS SHARE locks, i.e., only reads from the table can proceed in parallel with a transaction holding this lock mode. This lock mode is automatically acquired for UPDATE and DELETE in Greenplum Database (which is more restrictive locking than in regular PostgreSQL).
- **ACCESS EXCLUSIVE** — Conflicts with locks of all modes (ACCESS SHARE, ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, and ACCESS EXCLUSIVE). This mode guarantees that the holder is the only transaction accessing the table in any way. Acquired automatically by the ALTER TABLE, DROP TABLE, REINDEX, CLUSTER, and VACUUM FULL commands. This is also the default lock mode for LOCK TABLE statements that do not specify a mode explicitly.

**NOWAIT**

Specifies that LOCK TABLE should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is aborted.

---

**Notes**

LOCK TABLE ... IN ACCESS SHARE MODE requires SELECT privileges on the target table. All other forms of LOCK require UPDATE and/or DELETE privileges.

LOCK TABLE is useful only inside a transaction block (BEGIN/COMMIT pair), since the lock is dropped as soon as the transaction ends. A LOCK TABLE command appearing outside any transaction block forms a self-contained transaction, so the lock will be dropped as soon as it is obtained.

LOCK TABLE only deals with table-level locks, and so the mode names involving ROW are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, ROW EXCLUSIVE mode is a sharable table lock. Keep in mind that all the lock modes have identical semantics so far as LOCK TABLE is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see the FOR UPDATE/FOR SHARE clause in the [SELECT](#) reference documentation.

---

**Examples**

Obtain a SHARE lock on the *films* table when going to perform inserts into the *films\_user\_comments* table:

```
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
    WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
```

```
    (_id_, 'GREAT! I was waiting for it for so long!');  
COMMIT WORK;
```

Take a `SHARE ROW EXCLUSIVE` lock on a table when performing a delete operation:

```
BEGIN WORK;  
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;  
DELETE FROM films_user_comments WHERE id IN  
    (SELECT id FROM films WHERE rating < 5);  
DELETE FROM films WHERE rating < 5;  
COMMIT WORK;
```

---

## Compatibility

There is no `LOCK TABLE` in the SQL standard, which instead uses `SET TRANSACTION` to specify concurrency levels on transactions. Greenplum Database supports that too.

Except for `ACCESS SHARE`, `ACCESS EXCLUSIVE`, and `SHARE UPDATE EXCLUSIVE` lock modes, the Greenplum Database lock modes and the `LOCK TABLE` syntax are compatible with those present in Oracle.

---

## See Also

[BEGIN](#), [SET TRANSACTION](#), [SELECT](#)

---

## MOVE

Positions a cursor.

---

### Synopsis

```
MOVE [ forward_direction {FROM | IN} ] cursorname
```

*where direction can be empty or one of:*

```
NEXT
FIRST
LAST
ABSOLUTE count
RELATIVE count
count
ALL
FORWARD
FORWARD count
FORWARD ALL
```

---

### Description

MOVE repositions a cursor without retrieving any data. MOVE works exactly like the [FETCH](#) command, except it only positions the cursor and does not return rows.

Note that it is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using MOVE.

### Outputs

On successful completion, a MOVE command returns a command tag of the form

```
MOVE count
```

The count is the number of rows that a [FETCH](#) command with the same parameters would have returned (possibly zero).

---

### Parameters

***forward\_direction***

See [FETCH](#) for more information.

***cursorname***

The name of an open cursor.

---

### Examples

-- Start the transaction:

```
BEGIN;
```

-- Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

-- Move forward 5 rows in the cursor *mycursor*:

```
MOVE FORWARD 5 IN mycursor;
```

```
MOVE 5
```

--Fetch the next row after that (row 6):

```
FETCH 1 FROM mycursor;
```

```
code | title | did | date_prod | kind | len
-----+-----+-----+-----+-----+-----
P_303 | 48 Hrs | 103 | 1982-10-22 | Action | 01:37
(1 row)
```

-- Close the cursor and end the transaction:

```
CLOSE mycursor;
```

```
COMMIT;
```

---

## Compatibility

There is no MOVE statement in the SQL standard.

---

## See Also

[DECLARE](#), [FETCH](#), [CLOSE](#)

---

## PREPARE

Prepare a statement for execution.

---

### Synopsis

```
PREPARE name [ (datatype [, ...] ) ] AS statement
```

---

### Description

**PREPARE** creates a prepared statement, possibly with unbound parameters. A prepared statement is a server-side object that can be used to optimize performance. A prepared statement may be subsequently executed with a binding for its parameters. Greenplum Database may choose to replan the query for different executions of the same prepared statement.

Prepared statements can take parameters: values that are substituted into the statement when it is executed. When creating the prepared statement, refer to parameters by position, using \$1, \$2, etc. A corresponding list of parameter data types can optionally be specified. When a parameter's data type is not specified or is declared as unknown, the type is inferred from the context in which the parameter is used (if possible). When executing the statement, specify the actual values for these parameters in the **EXECUTE** statement.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. The prepared statement can be manually cleaned up using the **DEALLOCATE** command.

Prepared statements have the largest performance advantage when a single session is being used to execute a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, for example, if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to execute, the performance advantage of prepared statements will be less noticeable.

---

### Parameters

#### *name*

An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to execute or deallocate a previously prepared statement.

***datatype***

The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as unknown, it will be inferred from the context in which the parameter is used. To refer to the parameters in the prepared statement itself, use \$1, \$2, etc.

***statement***

Any SELECT, INSERT, UPDATE, DELETE, or VALUES statement.

---

**Notes**

In some situations, the query plan produced for a prepared statement will be inferior to the query plan that would have been chosen if the statement had been submitted and executed normally. This is because when the statement is planned and the planner attempts to determine the optimal query plan, the actual values of any parameters specified in the statement are unavailable. Greenplum Database collects statistics on the distribution of data in the table, and can use constant values in a statement to make guesses about the likely result of executing the statement. Since this data is unavailable when planning prepared statements with parameters, the chosen plan may be suboptimal. To examine the query plan Greenplum Database has chosen for a prepared statement, use EXPLAIN.

For more information on query planning and the statistics collected by Greenplum Database for that purpose, see the ANALYZE documentation.

You can see all available prepared statements of a session by querying the *pg\_prepared\_statements* system view.

---

**Examples**

Create a prepared statement for an INSERT statement, and then execute it:

```
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO
foo VALUES ($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a SELECT statement, and then execute it. Note that the data type of the second parameter is not specified, so it is inferred from the context in which \$2 is used:

```
PREPARE usrrptplan (int) AS SELECT * FROM users u, logs l
WHERE u.usrid=$1 AND u.usrid=l.usrid AND l.date = $2;
EXECUTE usrrptplan(1, current_date);
```

---

**Compatibility**

The SQL standard includes a PREPARE statement, but it is only for use in embedded SQL. This version of the PREPARE statement also uses a somewhat different syntax.

## REASSIGN OWNED

Changes the ownership of database objects owned by a database role.

---

### Synopsis

```
REASSIGN OWNED BY old_role [, ...] TO new_role
```

---

### Description

REASSIGN OWNED reassigns all the objects in the current database that are owned by *old\_role* to *new\_role*. Note that it does not change the ownership of the database itself.

---

### Parameters

#### *old\_role*

The name of a role. The ownership of all the objects in the current database owned by this role will be reassigned to *new\_role*.

#### *new\_role*

The name of the role that will be made the new owner of the affected objects.

---

### Notes

REASSIGN OWNED is often used to prepare for the removal of one or more roles. Because REASSIGN OWNED only affects the objects in the current database, it is usually necessary to execute this command in each database that contains objects owned by a role that is to be removed.

The DROP OWNED command is an alternative that drops all the database objects owned by one or more roles.

The REASSIGN OWNED command does not affect the privileges granted to the old roles in objects that are not owned by them. Use DROP OWNED to revoke those privileges.

---

### Examples

Reassign any database objects owned by the role named *sally* and *bob* to *admin*;

```
REASSIGN OWNED BY sally, bob TO admin;
```

---

### Compatibility

The REASSIGN OWNED statement is a Greenplum Database extension.

---

### See Also

[DROP OWNED](#), [DROP ROLE](#)

---

## REINDEX

Rebuilds indexes.

---

### Synopsis

```
REINDEX {INDEX | TABLE | DATABASE | SYSTEM} name
```

---

### Description

**REINDEX** rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use **REINDEX**:

- An index has become corrupted, and no longer contains valid data. Although in theory this should never happen, in practice indexes may become corrupted due to software bugs or hardware failures. **REINDEX** provides a recovery method.
- An index has become bloated, that it contains many empty or nearly-empty pages. This can occur with B-tree indexes in Greenplum Database under certain uncommon access patterns. **REINDEX** provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages.
- You have altered the fillfactor storage parameter for an index, and wish to ensure that the change has taken full effect.

---

### Parameters

#### **INDEX**

Recreate the specified index.

#### **TABLE**

Recreate all indexes of the specified table. If the table has a secondary TOAST table, that is reindexed as well.

#### **DATABASE**

Recreate all indexes within the current database. Indexes on shared system catalogs are skipped. This form of **REINDEX** cannot be executed inside a transaction block.

#### **SYSTEM**

Recreate all indexes on system catalogs within the current database. Indexes on user tables are not processed. Also, indexes on shared (global) system catalogs are skipped. This form of **REINDEX** cannot be executed inside a transaction block.

#### ***name***

The name of the specific index, table, or database to be reindexed. Index and table names may be schema-qualified. Presently, **REINDEX DATABASE** and **REINDEX SYSTEM** can only reindex the current database, so their parameter must match the current database's name.

---

## Notes

REINDEX is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different.

REINDEX locks out writes but not reads of the index's parent table. It also takes an exclusive lock on the specific index being processed, which will block reads that attempt to use that index. In contrast, DROP INDEX momentarily takes exclusive lock on the parent table, blocking both writes and reads. The subsequent CREATE INDEX locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads may be forced into expensive sequential scans. Another important point is that the drop/create approach invalidates any cached query plans that use the index, while REINDEX does not.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a database requires being the owner of the database (note that the owner can therefore rebuild indexes of tables owned by other users). Of course, superusers can always reindex anything.

If you suspect that shared global system catalog indexes are corrupted, they can only be reindexed in Greenplum utility mode. The typical symptom of a corrupt shared index is “index is not a btree” errors, or else the server crashes immediately at startup due to reliance on the corrupted indexes. Contact Greenplum Customer Support for assistance in this situation.

---

## Examples

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table *my\_table*:

```
REINDEX TABLE my_table;
```

---

## Compatibility

There is no REINDEX command in the SQL standard.

---

## See Also

[CREATE INDEX](#), [DROP INDEX](#), [VACUUM](#)

---

## RELEASE SAVEPOINT

Destroys a previously defined savepoint.

---

### Synopsis

```
RELEASE [SAVEPOINT] savepoint_name
```

---

### Description

RELEASE SAVEPOINT destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands executed after the savepoint was established. (To do that, see [ROLLBACK TO SAVEPOINT](#).) Destroying a savepoint when it is no longer needed may allow the system to reclaim some resources earlier than transaction end.

RELEASE SAVEPOINT also destroys all savepoints that were established *after* the named savepoint was established.

---

### Parameters

***savepoint\_name***

The name of the savepoint to destroy.

---

### Examples

To establish and later destroy a savepoint:

```
BEGIN;  
    INSERT INTO table1 VALUES (3);  
    SAVEPOINT my_savepoint;  
    INSERT INTO table1 VALUES (4);  
    RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

---

### Compatibility

This command conforms to the SQL standard. The standard specifies that the key word SAVEPOINT is mandatory, but Greenplum Database allows it to be omitted.

---

### See Also

[BEGIN](#), [SAVEPOINT](#), [ROLLBACK TO SAVEPOINT](#), [COMMIT](#)

---

## RESET

Restores the value of a system configuration parameter to the default value.

---

### Synopsis

```
RESET configuration_parameter
```

```
RESET ALL
```

---

### Description

RESET restores system configuration parameters to their default values. RESET is an alternative spelling for `SET configuration_parameter TO DEFAULT`.

The default value is defined as the value that the parameter would have had, had no SET ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the master `postgresql.conf` configuration file, command-line options, or per-database or per-user default settings. See “[Server Configuration Parameters](#)” on page 476 for more information.

---

### Parameters

*configuration\_parameter*

The name of a system configuration parameter. See “[Server Configuration Parameters](#)” on page 476 for details.

**ALL**

Resets all settable configuration parameters to their default values.

---

### Examples

Set the `work_mem` configuration parameter to its default value:

```
RESET work_mem;
```

---

### Compatibility

RESET is a Greenplum Database extension.

---

### See Also

[SET](#)

## REVOKE

Removes access privileges.

### Synopsis

```

REVOKE [GRANT OPTION FOR] { {SELECT | INSERT | UPDATE | DELETE
    | REFERENCES | TRIGGER} [,...] | ALL [PRIVILEGES] }
ON [TABLE] tablename [, ...]
FROM {rolename | PUBLIC} [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { {USAGE | SELECT | UPDATE} [,...]
    | ALL [PRIVILEGES] }
ON SEQUENCE sequencename [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { {CREATE | CONNECT
    | TEMPORARY | TEMP} [,...] | ALL [PRIVILEGES] }
ON DATABASE dbname [, ...]
FROM {rolename | PUBLIC} [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] {EXECUTE | ALL [PRIVILEGES]}
ON FUNCTION funcname ( [[argmode] [argname] argtype
    [, ...]] ) [, ...]
FROM {rolename | PUBLIC} [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] {USAGE | ALL [PRIVILEGES]}
ON LANGUAGE langname [, ...]
FROM {rolename | PUBLIC} [, ...]
[ CASCADE | RESTRICT ]

REVOKE [GRANT OPTION FOR] { {CREATE | USAGE} [,...]
    | ALL [PRIVILEGES] }
ON SCHEMA schemaname [, ...]
FROM {rolename | PUBLIC} [, ...]
[CASCADE | RESTRICT]

REVOKE [GRANT OPTION FOR] { CREATE | ALL [PRIVILEGES] }
ON TABLESPACE tablespacename [, ...]
FROM { rolename | PUBLIC } [, ...]
[CASCADE | RESTRICT]

REVOKE [ADMIN OPTION FOR] parent_role [, ...]
FROM member_role [, ...]
[CASCADE | RESTRICT]

```

---

## Description

REVOKE command revokes previously granted privileges from one or more roles. The key word PUBLIC refers to the implicitly defined group of all roles.

See the description of the [GRANT](#) command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to PUBLIC. Thus, for example, revoking SELECT privilege from PUBLIC does not necessarily mean that all roles have lost SELECT privilege on the object: those who have it granted directly or via another role will still have it.

If GRANT OPTION FOR is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a role holds a privilege with grant option and has granted it to other roles then the privileges held by those other roles are called dependent privileges. If the privilege or the grant option held by the first role is being revoked and dependent privileges exist, those dependent privileges are also revoked if CASCADE is specified, else the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of roles that is traceable to the role that is the subject of this REVOKE command. Thus, the affected roles may effectively keep the privilege if it was also granted through other roles.

When revoking membership in a role, GRANT OPTION is instead called ADMIN OPTION, but the behavior is similar.

---

## Parameters

See [GRANT](#).

---

## Examples

Revoke insert privilege for the public on table *films*:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from role *sally* on view *topten*. Note that this actually means revoke all privileges that the current role granted (if not a superuser).

```
REVOKE ALL PRIVILEGES ON topten FROM sally;
```

Revoke membership in role *admins* from user *joe*:

```
REVOKE admins FROM joe;
```

---

## Compatibility

The compatibility notes of the [GRANT](#) command also apply to REVOKE.

One of RESTRICT or CASCADE is required according to the standard, but Greenplum Database assumes RESTRICT by default.

---

## See Also

[GRANT](#)

---

## ROLLBACK

Aborts the current transaction.

---

### Synopsis

`ROLLBACK [WORK | TRANSACTION]`

---

### Description

`ROLLBACK` rolls back the current transaction and causes all the updates made by the transaction to be discarded.

---

### Parameters

`WORK`  
`TRANSACTION`

Optional key words. They have no effect.

---

### Notes

Use `COMMIT` to successfully end the current transaction.

Issuing `ROLLBACK` when not inside a transaction does no harm, but it will provoke a warning message.

---

### Examples

To discard all changes made in the current transaction:

```
ROLLBACK;
```

---

### Compatibility

The SQL standard only specifies the two forms `ROLLBACK` and `ROLLBACK WORK`. Otherwise, this command is fully conforming.

---

### See Also

[BEGIN](#), [COMMIT](#), [SAVEPOINT](#), [ROLLBACK TO SAVEPOINT](#)

---

## ROLLBACK TO SAVEPOINT

Rolls back the current transaction to a savepoint.

---

### Synopsis

```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name
```

---

### Description

This command will roll back all commands that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

---

### Parameters

**WORK**  
**TRANSACTION**

Optional key words. They have no effect.

***savepoint\_name***

The name of a savepoint to roll back to.

---

### Notes

Use `RELEASE SAVEPOINT` to destroy a savepoint without discarding the effects of commands executed after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a `FETCH` command inside a savepoint that is later rolled back, the cursor position remains at the position that `FETCH` left it pointing to (that is, `FETCH` is not rolled back). Closing a cursor is not undone by rolling back, either. A cursor whose execution causes a transaction to abort is put in a can't-execute state, so while the transaction can be restored using `ROLLBACK TO SAVEPOINT`, the cursor can no longer be used.

---

### Examples

To undo the effects of the commands executed after *my\_savepoint* was established:

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by a savepoint rollback:

```
BEGIN;  
DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;
```

```

SAVEPOINT foo;
FETCH 1 FROM foo;
column
-----
          1
ROLLBACK TO SAVEPOINT foo;
FETCH 1 FROM foo;
column
-----
          2
COMMIT;

```

---

### Compatibility

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but Greenplum Database (and Oracle) allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [NO] CHAIN` which is not currently supported by Greenplum Database. Otherwise, this command conforms to the SQL standard.

---

### See Also

[BEGIN](#), [COMMIT](#), [SAVEPOINT](#), [RELEASE SAVEPOINT](#), [ROLLBACK](#)

---

## SAVEPOINT

Defines a new savepoint within the current transaction.

---

### Synopsis

```
SAVEPOINT savepoint_name
```

---

### Description

SAVEPOINT establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are executed after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

---

### Parameters

***savepoint\_name***

The name of the new savepoint.

---

### Notes

Use [ROLLBACK TO SAVEPOINT](#) to rollback to a savepoint. Use [RELEASE SAVEPOINT](#) to destroy a savepoint, keeping the effects of commands executed after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

---

### Examples

To establish a savepoint and later undo the effects of all commands executed after it was established:

```
BEGIN;
    INSERT INTO table1 VALUES (1);
    SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (2);
    ROLLBACK TO SAVEPOINT my_savepoint;
    INSERT INTO table1 VALUES (3);
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;
    INSERT INTO table1 VALUES (3);
```

```
SAVEPOINT my_savepoint;  
INSERT INTO table1 VALUES (4);  
RELEASE SAVEPOINT my_savepoint;  
COMMIT;
```

The above transaction will insert both 3 and 4.

---

## Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In Greenplum Database, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint will cause the older one to again become accessible to [ROLLBACK TO SAVEPOINT](#) and [RELEASE SAVEPOINT](#).) Otherwise, SAVEPOINT is fully SQL conforming.

---

## See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK](#), [RELEASE SAVEPOINT](#), [ROLLBACK TO SAVEPOINT](#)

## SELECT

Retrieves rows from a table or view.

### Synopsis

```

                ( column_definition [, ...] )
```

```

from_item [NATURAL] join_type from_item
        [ON join_condition | USING ( join_column [, ...] )]

```

---

## Description

**SELECT** retrieves rows from zero or more tables. The general processing of **SELECT** is as follows:

1. All elements in the **FROM** list are computed. (Each element in the **FROM** list is a real or virtual table.) If more than one element is specified in the **FROM** list, they are cross-joined together.
2. If the **WHERE** clause is specified, all rows that do not satisfy the condition are eliminated from the output.
3. If the **GROUP BY** clause is specified, the output is divided into groups of rows that match on one or more of the defined grouping elements. If the **HAVING** clause is present, it eliminates groups that do not satisfy the given condition.
4. If a window expression is specified (and optional **WINDOW** clause), the output is organized according to the positional (row) or value-based (range) window frame.
5. **DISTINCT** eliminates duplicate rows from the result. **DISTINCT ON** eliminates rows that match on all the specified expressions. **ALL** (the default) will return all candidate rows, including duplicates.
6. The actual output rows are computed using the **SELECT** output expressions for each selected row.
7. Using the operators **UNION**, **INTERSECT**, and **EXCEPT**, the output of more than one **SELECT** statement can be combined to form a single result set. The **UNION** operator returns all rows that are in one or both of the result sets. The **INTERSECT** operator returns all rows that are strictly in both result sets. The **EXCEPT** operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless **ALL** is specified.
8. If the **ORDER BY** clause is specified, the returned rows are sorted in the specified order. If **ORDER BY** is not given, the rows are returned in whatever order the system finds fastest to produce.
9. If the **LIMIT** or **OFFSET** clause is specified, the **SELECT** statement only returns a subset of the result rows.
10. If **FOR UPDATE** or **FOR SHARE** is specified, the **SELECT** statement locks the entire table against concurrent updates.

You must have **SELECT** privilege on a table to read its values. The use of **FOR UPDATE** or **FOR SHARE** requires **UPDATE** privilege as well.

---

## Parameters

### The SELECT List

The `SELECT` list (between the key words `SELECT` and `FROM`) specifies expressions that form the output rows of the `SELECT` statement. The expressions can (and usually do) refer to columns computed in the `FROM` clause.

Using the clause `[AS] output_name`, another name can be specified for an output column. This name is primarily used to label the column for display. It can also be used to refer to the column's value in `ORDER BY` and `GROUP BY` clauses, but not in the `WHERE` or `HAVING` clauses; there you must write out the expression instead. The `AS` keyword is optional in most cases (such as when declaring an alias for column names, constants, function calls, and simple unary operator expressions). In cases where the declared alias is a reserved SQL keyword, the `output_name` must be enclosed in double quotes to avoid ambiguity.

An *expression* in the `SELECT` list can be a constant value, a column reference, an operator invocation, a function call, an aggregate expression, a window expression, a scalar subquery, and so on. A number of constructs can be classified as an expression but do not follow any general syntax rules. These generally have the semantics of a function or operator. For information about SQL value expressions and function calls, see the *Greenplum Database Database Administrator Guide*.

Instead of an expression, `*` can be written in the output list as a shorthand for all the columns of the selected rows. Also, one can write `table_name.*` as a shorthand for the columns coming from just that table.

### The FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added to restrict the returned rows to a small subset of the Cartesian product. The `FROM` clause can contain the following elements:

#### **`table_name`**

The name (optionally schema-qualified) of an existing table or view. If `ONLY` is specified, only that table is scanned. If `ONLY` is not specified, the table and all its descendant tables (if any) are scanned.

#### **`alias`**

A substitute name for the `FROM` item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given `FROM foo AS f`, the remainder of the `SELECT` must refer to this `FROM` item as `f` not `foo`. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

#### **`select`**

A sub-`SELECT` can appear in the `FROM` clause. This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. Note that the sub-`SELECT` must be surrounded by parentheses, and an alias must be

provided for it. A `VALUES` command can also be used here. See “[Nonstandard Clauses](#)” on page 291 for limitations of using correlated sub-selects in Greenplum Database.

#### ***function\_name***

Function calls can appear in the `FROM` clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though its output were created as a temporary table for the duration of this single `SELECT` command. An alias may also be used. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function’s composite return type. If the function has been defined as returning the record data type, then an alias or the key word `AS` must be present, followed by a column definition list in the form ( `column_name data_type [, ... ]` ). The column definition list must match the actual number and types of columns returned by the function.

#### ***join\_type***

One of:

- `[INNER] JOIN`
- `LEFT [OUTER] JOIN`
- `RIGHT [OUTER] JOIN`
- `FULL [OUTER] JOIN`
- `CROSS JOIN`

For the `INNER` and `OUTER` join types, a join condition must be specified, namely exactly one of `NATURAL`, `ON join_condition`, or `USING (join_column [, ... ])`. See below for the meaning. For `CROSS JOIN`, none of these clauses may appear.

A `JOIN` clause combines two `FROM` items. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, `JOINS` nest left-to-right. In any case `JOIN` binds more tightly than the commas separating `FROM` items.

`CROSS JOIN` and `INNER JOIN` produce a simple Cartesian product, the same result as you get from listing the two items at the top level of `FROM`, but restricted by the join condition (if any). `CROSS JOIN` is equivalent to `INNER JOIN ON (TRUE)`, that is, no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you could not do with plain `FROM` and `WHERE`.

`LEFT OUTER JOIN` returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the `JOIN` clause’s own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, `RIGHT OUTER JOIN` returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a `LEFT OUTER JOIN` by switching the left and right inputs.

**FULL OUTER JOIN** returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

#### **ON *join\_condition***

*join\_condition* is an expression resulting in a value of type `boolean` (similar to a `WHERE` clause) that specifies which rows in a join are considered to match.

#### **USING (*join\_column* [, ...])**

A clause of the form `USING ( a, b, ... )` is shorthand for `ON left_table.a = right_table.a AND left_table.b = right_table.b ....` Also, `USING` implies that only one of each pair of equivalent columns will be included in the join output, not both.

#### **NATURAL**

`NATURAL` is shorthand for a `USING` list that mentions all columns in the two tables that have the same names.

### **The WHERE Clause**

The optional `WHERE` clause has the general form:

```
WHERE condition
```

Where *condition* is any expression that evaluates to a result of type `boolean`. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

### **The GROUP BY Clause**

The optional `GROUP BY` clause has the general form:

```
GROUP BY grouping_element [, ...]
```

where *grouping\_element* can be one of:

```
(  
  expression  
  ROLLUP (expression [,...])  
  CUBE (expression [,...])  
  GROUPING SETS ((grouping_element [, ...]))
```

`GROUP BY` will condense into a single row all selected rows that share the same values for the grouped expressions. *expression* can be an input column name, or the name or ordinal number of an output column (`SELECT` list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a `GROUP BY` name will be interpreted as an input-column name rather than an output column name.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group (whereas without `GROUP BY`, an aggregate produces a single value computed across all the selected rows). When

`GROUP BY` is present, it is not valid for the `SELECT` list expressions to refer to ungrouped columns except within aggregate functions, since there would be more than one possible value to return for an ungrouped column.

Greenplum Database has the following additional OLAP grouping extensions (often referred to as *supergroups*):

### ROLLUP

A `ROLLUP` grouping is an extension to the `GROUP BY` clause that creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). `ROLLUP` takes an ordered list of grouping columns, calculates the standard aggregate values specified in the `GROUP BY` clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total. A `ROLLUP` grouping can be thought of as a series of grouping sets. For example:

```
GROUP BY ROLLUP (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a), () )
```

Notice that the  $n$  elements of a `ROLLUP` translate to  $n+1$  grouping sets. Also, the order in which the grouping expressions are specified is significant in a `ROLLUP`.

### CUBE

A `CUBE` grouping is an extension to the `GROUP BY` clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In terms of multidimensional analysis, `CUBE` generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example:

```
GROUP BY CUBE (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a,c), (b,c), (a),  
  (b), (c), () )
```

Notice that  $n$  elements of a `CUBE` translate to  $2^n$  grouping sets. Consider using `CUBE` in any situation requiring cross-tabular reports. `CUBE` is typically most suitable in queries that use columns from multiple dimensions rather than columns representing different levels of a single dimension. For instance, a commonly requested cross-tabulation might need subtotals for all the combinations of month, state, and product.

### GROUPING SETS

You can selectively specify the set of groups that you want to create using a `GROUPING SETS` expression within a `GROUP BY` clause. This allows precise specification across multiple dimensions without computing a whole `ROLLUP` or `CUBE`. For example:

```
GROUP BY GROUPING SETS( (a,c), (a,b) )
```

If using the grouping extension clauses `ROLLUP`, `CUBE`, or `GROUPING SETS`, two challenges arise. First, how do you determine which result rows are subtotals, and then the exact level of aggregation for a given subtotal. Or, how do you differentiate between result rows that contain both stored `NULL` values and “`NULL`” values created by the `ROLLUP` or `CUBE`. Secondly, when duplicate grouping sets are specified in the `GROUP BY` clause, how do you determine which result rows are duplicates? There are two additional grouping functions you can use in the `SELECT` list to help with this:

- **grouping(column [, ...])** The grouping function can be applied to one or more grouping attributes to distinguish super-aggregated rows from regular grouped rows. This can be helpful in distinguishing a “`NULL`” representing the set of all values in a super-aggregated row from a `NULL` value in a regular row. Each argument in this function produces a bit — either 1 or 0, where 1 means the result row is super-aggregated, and 0 means the result row is from a regular grouping. The `grouping` function returns an integer by treating these bits as a binary number and then converting it to a base-10 integer.
- **group\_id()** For grouping extension queries that contain duplicate grouping sets, the `group_id` function is used to identify duplicate rows in the output. All *unique* grouping set output rows will have a `group_id` value of 0. For each duplicate grouping set detected, the `group_id` function assigns a `group_id` number greater than 0. All output rows in a particular duplicate grouping set are identified by the same `group_id` number.

## The WINDOW Clause

The `WINDOW` clause is used to define a window that can be used in the `OVER()` expression of a window function such as `rank` or `avg`. For example:

```
SELECT vendor, rank() OVER (mywindow) FROM sale
GROUP BY vendor
WINDOW mywindow AS (ORDER BY sum(prc*qty));
```

A `WINDOW` clause is has this general form:

```
WINDOW window_name AS (window_specification)
where window_specification can be:
[window_name]
[PARTITION BY expression [, ...]]
[ORDER BY expression [ASC | DESC | USING operator] [, ...]]
  [{RANGE | ROWS}
    { UNBOUNDED PRECEDING
      | expression PRECEDING
      | CURRENT ROW
      | BETWEEN window_frame_bound AND window_frame_bound }]]
```

where *window\_frame\_bound* can be one of:

```
UNBOUNDED PRECEDING
expression PRECEDING
CURRENT ROW
expression FOLLOWING
UNBOUNDED FOLLOWING
```

***window\_name***

Gives a name to the window specification.

**PARTITION BY**

The **PARTITION BY** clause organizes the result set into logical groups based on the unique values of the specified expression. When used with window functions, the functions are applied to each partition independently. For example, if you follow **PARTITION BY** with a column name, the result set is partitioned by the distinct values of that column. If omitted, the entire result set is considered one partition.

**ORDER BY**

The **ORDER BY** clause defines how to sort the rows in each partition of the result set. If omitted, rows are returned in whatever order is most efficient and may vary.

**Note:** Columns of data types that lack a coherent ordering, such as `time`, are not good candidates for use in the **ORDER BY** clause of a window specification. Time, with or without time zone, lacks a coherent ordering because addition and subtraction do not have the expected effects. For example, the following is not generally true: `x::time < x::time + '2 hour'::interval`

**ROWS | RANGE**

Use either a **ROWS** or **RANGE** clause to express the bounds of the window. The window bound can be one, many, or all rows of a partition. You can express the bound of the window either in terms of a range of data values offset from the value in the current row (**RANGE**), or in terms of the number of rows offset from the current row (**ROWS**). When using the **RANGE** clause, you must also use an **ORDER BY** clause. This is because the calculation performed to produce the window requires that the values be sorted. Additionally, the **ORDER BY** clause cannot contain more than one expression, and the expression must result in either a date or a numeric value. When using the **ROWS** or **RANGE** clauses, if you specify only a starting row, the current row is used as the last row in the window.

**PRECEDING**

The **PRECEDING** clause defines the first row of the window using the current row as a reference point. The starting row is expressed in terms of the number of rows preceding the current row. For example, in the case of **ROWS** framing, `5 PRECEDING` sets the window to start with the fifth row preceding the current row. In the case of **RANGE** framing, it sets the window to start with the first row whose ordering column value precedes that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the first row within 5 days before the current row. **UNBOUNDED PRECEDING** sets the first row in the window to be the first row in the partition.

**BETWEEN**

The **BETWEEN** clause defines the first and last row of the window, using the current row as a reference point. First and last rows are expressed in terms of the number of rows preceding and following the current row, respectively. For example, `BETWEEN 3 PRECEDING AND 5 FOLLOWING` sets the window to start with the third row preceding the current row, and end with the fifth row following the current row. Use **BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED**

`FOLLOWING` to set the first and last rows in the window to be the first and last row in the partition, respectively. This is equivalent to the default behavior if no `ROW` or `RANGE` clause is specified.

#### **FOLLOWING**

The `FOLLOWING` clause defines the last row of the window using the current row as a reference point. The last row is expressed in terms of the number of rows following the current row. For example, in the case of `ROWS` framing, 5 `FOLLOWING` sets the window to end with the fifth row following the current row. In the case of `RANGE` framing, it sets the window to end with the last row whose ordering column value follows that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the last row within 5 days after the current row. Use `UNBOUNDED FOLLOWING` to set the last row in the window to be the last row in the partition.

If you do not specify a `ROW` or a `RANGE` clause, the window bound starts with the first row in the partition (`UNBOUNDED PRECEDING`) and ends with the current row (`CURRENT ROW`) if `ORDER BY` is used. If an `ORDER BY` is not specified, the window starts with the first row in the partition (`UNBOUNDED PRECEDING`) and ends with last row in the partition (`UNBOUNDED FOLLOWING`).

### **The HAVING Clause**

The optional `HAVING` clause has the general form:

```
HAVING condition
```

Where *condition* is the same as specified for the `WHERE` clause. `HAVING` eliminates group rows that do not satisfy the condition. `HAVING` is different from `WHERE`: `WHERE` filters individual rows before the application of `GROUP BY`, while `HAVING` filters group rows created by `GROUP BY`. Each column referenced in *condition* must unambiguously reference a grouping column, unless the reference appears within an aggregate function.

The presence of `HAVING` turns a query into a grouped query even if there is no `GROUP BY` clause. This is the same as what happens when the query contains aggregate functions but no `GROUP BY` clause. All the selected rows are considered to form a single group, and the `SELECT` list and `HAVING` clause can only reference table columns from within aggregate functions. Such a query will emit a single row if the `HAVING` condition is true, zero rows if it is not true.

### **The UNION Clause**

The `UNION` clause has this general form:

```
select_statement UNION [ALL] select_statement
```

Where *select\_statement* is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR UPDATE`, or `FOR SHARE` clause. (`ORDER BY` and `LIMIT` can be attached to a subquery expression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the `UNION`, not to its right-hand input expression.)

The UNION operator computes the set union of the rows returned by the involved SELECT statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two SELECT statements that represent the direct operands of the UNION must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of UNION does not contain any duplicate rows unless the ALL option is specified. ALL prevents elimination of duplicates. (Therefore, UNION ALL is usually significantly quicker than UNION; use ALL when you can.)

Multiple UNION operators in the same SELECT statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, FOR UPDATE and FOR SHARE may not be specified either for a UNION result or for any input of a UNION.

### The INTERSECT Clause

The INTERSECT clause has this general form:

```
select_statement INTERSECT [ALL] select_statement
```

Where *select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR UPDATE, or FOR SHARE clause.

The INTERSECT operator computes the set intersection of the rows returned by the involved SELECT statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of INTERSECT does not contain any duplicate rows unless the ALL option is specified. With ALL, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\min(m, n)$  times in the result set.

Multiple INTERSECT operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. INTERSECT binds more tightly than UNION. That is, A UNION B INTERSECT C will be read as A UNION (B INTERSECT C).

Currently, FOR UPDATE and FOR SHARE may not be specified either for an INTERSECT result or for any input of an INTERSECT.

### The EXCEPT Clause

The EXCEPT clause has this general form:

```
select_statement EXCEPT [ALL] select_statement
```

Where *select\_statement* is any SELECT statement without an ORDER BY, LIMIT, FOR UPDATE, or FOR SHARE clause.

The EXCEPT operator computes the set of rows that are in the result of the left SELECT statement but not in the result of the right one.

The result of EXCEPT does not contain any duplicate rows unless the ALL option is specified. With ALL, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\max(m-n, 0)$  times in the result set.

Multiple EXCEPT operators in the same SELECT statement are evaluated left to right, unless parentheses dictate otherwise. EXCEPT binds at the same level as UNION.

Currently, `FOR UPDATE` and `FOR SHARE` may not be specified either for an `EXCEPT` result or for any input of an `EXCEPT`.

### The ORDER BY Clause

The optional `ORDER BY` clause has this general form:

```
ORDER BY expression [ASC | DESC | USING operator] [, ...]
```

Where *expression* can be the name or ordinal number of an output column (`SELECT` list item), or it can be an arbitrary expression formed from input-column values.

The `ORDER BY` clause causes the result rows to be sorted according to the specified expressions. If two rows are equal according to the left-most expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

The ordinal number refers to the ordinal (left-to-right) position of the result column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to a result column using the `AS` clause.

It is also possible to use arbitrary expressions in the `ORDER BY` clause, including columns that do not appear in the `SELECT` result list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an `ORDER BY` clause applying to the result of a `UNION`, `INTERSECT`, or `EXCEPT` clause may only specify an output column name or number, not an expression.

If an `ORDER BY` expression is a simple name that matches both a result column name and an input column name, `ORDER BY` will interpret it as the result column name. This is the opposite of the choice that `GROUP BY` will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one may add the key word `ASC` (ascending) or `DESC` (descending) after any expression in the `ORDER BY` clause. If not specified, `ASC` is assumed by default. Alternatively, a specific ordering operator name may be specified in the `USING` clause. `ASC` is usually equivalent to `USING <` and `DESC` is usually equivalent to `USING >`. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

The null value sorts higher than any other value. In other words, with ascending sort order, null values sort at the end, and with descending sort order, null values sort at the beginning.

Character-string data is sorted according to the locale-specific collation order that was established when the Greenplum Database system was initialized.

### The DISTINCT Clause

If `DISTINCT` is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). `ALL` specifies the opposite: all rows are kept. `ALL` is the default.

`DISTINCT ON ( expression [, ...] )` keeps only the first row of each set of rows where the given expressions evaluate to equal. The `DISTINCT ON` expressions are interpreted using the same rules as for `ORDER BY`. Note that the ‘first row’ of each set is unpredictable unless `ORDER BY` is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report FROM
weather_reports ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used `ORDER BY` to force descending order of time values for each location, we would have gotten a report from an unpredictable time for each location.

The `DISTINCT ON` expression(s) must match the left-most `ORDER BY` expression(s). The `ORDER BY` clause will normally contain additional expression(s) that determine the desired precedence of rows within each `DISTINCT ON` group.

When Greenplum Database processes queries that contain the `DISTINCT` clause, the queries are transformed into `GROUP BY` queries. In many cases, the transformation provides significant performance gains. However, when the number of distinct values is close to the total number of rows, the transformation might result in the generation of a multi-level grouping plan. In this case, there is an expected performance degradation because of the overhead introduced by the lower aggregation level.

### The LIMIT Clause

The `LIMIT` clause consists of two independent sub-clauses:

```
LIMIT { count | ALL }
      OFFSET start
```

Where *count* specifies the maximum number of rows to return, while *start* specifies the number of rows to skip before starting to return rows. When both are specified, start rows are skipped before starting to count the count rows to be returned.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query’s rows — you may be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don’t know what ordering unless you specify `ORDER BY`.

The query planner takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result will give inconsistent results unless you enforce a predictable result ordering with `ORDER BY`. This is not a defect; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

### FOR UPDATE/FOR SHARE Clause

The `FOR UPDATE` clause has this form:

```
FOR UPDATE [OF table_name [, ...]] [NOWAIT]
```

The closely related `FOR SHARE` clause has this form:

```
FOR SHARE [OF table_name [, ...]] [NOWAIT]
```

FOR UPDATE causes the tables accessed by the SELECT statement to be locked as though for update. This prevents the table from being modified or deleted by other transactions until the current transaction ends. That is, other transactions that attempt UPDATE, DELETE, or SELECT FOR UPDATE of this table will be blocked until the current transaction ends. Also, if an UPDATE, DELETE, or SELECT FOR UPDATE from another transaction has already locked a selected table, SELECT FOR UPDATE will wait for the other transaction to complete, and will then lock and return the updated table.

To prevent the operation from waiting for other transactions to commit, use the NOWAIT option. SELECT FOR UPDATE NOWAIT reports an error, rather than waiting, if a selected row cannot be locked immediately. Note that NOWAIT applies only to the row-level lock(s) — the required ROW SHARE table-level lock is still taken in the ordinary way. You can use the NOWAIT option of LOCK if you need to acquire the table-level lock without waiting (see [LOCK](#)).

FOR SHARE behaves similarly, except that it acquires a shared rather than exclusive lock on the table. A shared lock blocks other transactions from performing UPDATE, DELETE, or SELECT FOR UPDATE on the table, but it does not prevent them from performing SELECT FOR SHARE.

If specific tables are named in FOR UPDATE or FOR SHARE, then only those tables are locked; any other tables used in the SELECT are simply read as usual. A FOR UPDATE or FOR SHARE clause without a table list affects all tables used in the command. If FOR UPDATE or FOR SHARE is applied to a view or subquery, it affects all tables used in the view or subquery.

Multiple FOR UPDATE and FOR SHARE clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by both FOR UPDATE and FOR SHARE clauses, then it is processed as FOR UPDATE. Similarly, a table is processed as NOWAIT if that is specified in any of the clauses affecting it.

---

## Examples

To join the table *films* with the table *distributors*:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind FROM
distributors d, films f WHERE f.did = d.did
```

To sum the column *length* of all films and group the results by *kind*:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind;
```

To sum the column *length* of all films, group the results by *kind* and show those group totals that are less than 5 hours:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind
HAVING sum(length) < interval '5 hours';
```

Calculate the subtotals and grand totals of all sales for movie *kind* and *distributor*.

```
SELECT kind, distributor, sum(prc*qty) FROM sales
GROUP BY ROLLUP(kind, distributor)
```

```
ORDER BY 1,2,3;
```

Calculate the rank of movie distributors based on total sales:

```
SELECT distributor, sum(prc*qty),
       rank() OVER (ORDER BY sum(prc*qty) DESC)
FROM sale
GROUP BY distributor ORDER BY 2 DESC;
```

The following two examples are identical ways of sorting the individual results according to the contents of the second column (*name*):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

The next example shows how to obtain the union of the tables *distributors* and *actors*, restricting the results to those that begin with the letter *W* in each table. Only distinct rows are wanted, so the key word `ALL` is omitted:

```
SELECT distributors.name FROM distributors WHERE
distributors.name LIKE 'W%' UNION SELECT actors.name FROM
actors WHERE actors.name LIKE 'W%';
```

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors
AS $$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE
SQL;
SELECT * FROM distributors(111);
```

```
CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS
$$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE
SQL;
SELECT * FROM distributors_2(111) AS (dist_id int, dist_name
text);
```

---

## Compatibility

The `SELECT` statement is compatible with the SQL standard, but there are some extensions and some missing features.

### Omitted FROM Clauses

Greenplum Database allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions. For example:

```
SELECT 2+2;
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Note that if a `FROM` clause is not specified, the query cannot reference any database tables. For compatibility with applications that rely on this behavior the *add\_missing\_from* configuration variable can be enabled.

### The AS Key Word

In the SQL standard, the optional key word `AS` is just noise and can be omitted without affecting the meaning. The Greenplum Database parser requires this key word when renaming output columns because the type extensibility features lead to parsing ambiguities without it. `AS` is optional in `FROM` items, however.

### Namespace Available to GROUP BY and ORDER BY

In the SQL-92 standard, an `ORDER BY` clause may only use result column names or numbers, while a `GROUP BY` clause may only use expressions based on input column names. Greenplum Database extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). Greenplum Database also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression will always be taken as input-column names, not as result-column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, Greenplum Database will interpret an `ORDER BY` or `GROUP BY` expression the same way SQL:1999 does.

### Nonstandard Clauses

The clauses `DISTINCT ON`, `LIMIT`, and `OFFSET` are not defined in the SQL standard.

### Limited Use of STABLE and VOLATILE Functions

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as `STABLE` or `VOLATILE` cannot be executed at the segment database level if it contains SQL or modifies the database in any way. See [CREATE FUNCTION](#) for more information.

---

## SELECT INTO

Defines a new table from the results of a query.

---

### Synopsis

```
SELECT [ALL | DISTINCT [ON ( expression [, ...] )]]
      * | expression [AS output_name] [, ...]
INTO [TEMPORARY | TEMP] [TABLE] new_table
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY expression [, ...]]
[HAVING condition [, ...]]
[{UNION | INTERSECT | EXCEPT} [ALL] select]
[ORDER BY expression [ASC | DESC | USING operator] [, ...]]
[LIMIT {count | ALL}]
[OFFSET start]
[FOR {UPDATE | SHARE} [OF table_name [, ...]] [NOWAIT]
[...]]
```

---

### Description

`SELECT INTO` creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal `SELECT`. The new table's columns have the names and data types associated with the output columns of the `SELECT`.

---

### Parameters

The majority of parameters for `SELECT INTO` are the same as [SELECT](#).

**TEMPORARY**  
**TEMP**

If specified, the table is created as a temporary table.

***new\_table***

The name (optionally schema-qualified) of the table to be created.

---

### Examples

Create a new table *films\_recent* consisting of only recent entries from the table *films*:

```
SELECT * INTO films_recent FROM films WHERE date_prod >=
'2006-01-01';
```

---

### Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. The Greenplum Database usage of `SELECT INTO` to represent table creation is historical. It is best to use [CREATE TABLE AS](#) for this purpose in new applications.

## SET

Changes the value of a Greenplum Database configuration parameter.

---

### Synopsis

```
SET [SESSION | LOCAL] configuration_parameter {TO | =} value |
'value' | DEFAULT}

SET [SESSION | LOCAL] TIME ZONE {timezone | LOCAL | DEFAULT}
```

---

### Description

The SET command changes server configuration parameters. Any configuration parameter classified as a *session* parameter can be changed on-the-fly with SET. SET affects only the value used by the current session.

If SET or SET SESSION is issued within a transaction that is later aborted, the effects of the SET command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another SET.

The effects of SET LOCAL last only till the end of the current transaction, whether committed or not. A special case is SET followed by SET LOCAL within a single transaction: the SET LOCAL value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the SET value will take effect.

See “[Server Configuration Parameters](#)” on page 476 for information about server parameters.

---

### Parameters

#### SESSION

Specifies that the command takes effect for the current session. This is the default.

#### LOCAL

Specifies that the command takes effect for only the current transaction. After COMMIT or ROLLBACK, the session-level setting takes effect again. Note that SET LOCAL will appear to have no effect if it is executed outside of a transaction.

#### *configuration\_parameter*

The name of a Greenplum Database configuration parameter. Only parameters classified as *session* can be changed with SET. See “[Server Configuration Parameters](#)” on page 476 for details.

#### *value*

New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these. DEFAULT can be used to specify resetting the parameter to its default value. If specifying memory sizing or time units, enclose the value in single quotes.

**TIME ZONE**

SET TIME ZONE *value* is an alias for SET `timezone TO value`. The syntax SET TIME ZONE allows special syntax for the time zone specification. Here are examples of valid values:

```
'PST8PDT'
```

```
'Europe/Rome'
```

```
-7 (time zone 7 hours west from UTC)
```

```
INTERVAL '-08:00' HOUR TO MINUTE (time zone 8 hours west from UTC).
```

**LOCAL  
DEFAULT**

Set the time zone to your local time zone (the one that the server's operating system defaults to). See the [Time zone section of the PostgreSQL documentation](#) for more information about time zones in Greenplum Database.

---

**Examples**

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Increase work memory to 200 MB:

```
SET work_mem TO '200MB';
```

Set the style of date to traditional POSTGRES with “day before month” input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for San Mateo, California:

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

---

**Compatibility**

SET TIME ZONE extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while Greenplum Database allows more flexible time-zone specifications. All other SET features are Greenplum Database extensions.

[RESET](#), [SHOW](#)

---

## SET ROLE

Sets the current role identifier of the current session.

---

### Synopsis

```
SET [SESSION | LOCAL] ROLE rolename
SET [SESSION | LOCAL] ROLE NONE
RESET ROLE
```

---

### Description

This command sets the current role identifier of the current SQL-session context to be *rolename*. The role name may be written as either an identifier or a string literal. After `SET ROLE`, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified *rolename* must be a role that the current session user is a member of. If the session user is a superuser, any role can be selected.

The `NONE` and `RESET` forms reset the current role identifier to be the current session role identifier. These forms may be executed by any user.

---

### Parameters

#### **SESSION**

Specifies that the command takes effect for the current session. This is the default.

#### **LOCAL**

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside of a transaction.

#### ***rolename***

The name of a role to use for permissions checking in this session.

#### **NONE**

#### **RESET**

Reset the current role identifier to be the current session role identifier (that of the role used to log in).

---

### Notes

Using this command, it is possible to either add privileges or restrict privileges. If the session user role has the `INHERITS` attribute, then it automatically has all the privileges of every role that it could `SET ROLE` to; in this case `SET ROLE` effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other

hand, if the session user role has the `NOINHERITS` attribute, `SET ROLE` drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to `SET ROLE` to a non-superuser role, she loses her superuser privileges.

`SET ROLE` has effects comparable to `SET SESSION AUTHORIZATION`, but the privilege checks involved are quite different. Also, `SET SESSION AUTHORIZATION` determines which roles are allowable for later `SET ROLE` commands, whereas changing roles with `SET ROLE` does not change the set of roles allowed to a later `SET ROLE`.

---

### Examples

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
    peter      |    peter
```

```
SET ROLE 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
    peter      |    paul
```

---

### Compatibility

Greenplum Database allows identifier syntax (*rolename*), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The `SESSION` and `LOCAL` modifiers are a Greenplum Database extension, as is the `RESET` syntax.

---

### See Also

[SET SESSION AUTHORIZATION](#)

---

## SET SESSION AUTHORIZATION

Sets the session role identifier and the current role identifier of the current session.

---

### Synopsis

```
SET [SESSION | LOCAL] SESSION AUTHORIZATION rolename
SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT
RESET SESSION AUTHORIZATION
```

---

### Description

This command sets the session role identifier and the current role identifier of the current SQL-session context to be *rolename*. The role name may be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session role identifier is initially set to be the (possibly authenticated) role name provided by the client. The current role identifier is normally equal to the session user identifier, but may change temporarily in the context of `setuid` functions and similar mechanisms; it can also be changed by [SET ROLE](#). The current user identifier is relevant for permission checking.

The session user identifier may be changed only if the initial session user (the authenticated user) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The `DEFAULT` and `RESET` forms reset the session and current user identifiers to be the originally authenticated user name. These forms may be executed by any user.

---

### Parameters

#### SESSION

Specifies that the command takes effect for the current session. This is the default.

#### LOCAL

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is executed outside of a transaction.

#### *rolename*

The name of the role to assume.

#### NONE

#### RESET

Reset the session and current role identifiers to be that of the role used to log in.

---

**Examples**

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
    peter      |    peter
```

```
SET SESSION AUTHORIZATION 'paul';
```

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
    paul      |    paul
```

---

**Compatibility**

The SQL standard allows some other expressions to appear in place of the literal *rolename*, but these options are not important in practice. Greenplum Database allows identifier syntax (“*rolename*”), which SQL does not. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The `SESSION` and `LOCAL` modifiers are a Greenplum Database extension, as is the `RESET` syntax.

---

**See Also**

[SET ROLE](#)

---

## SET TRANSACTION

Sets the characteristics of the current transaction.

---

### Synopsis

```
SET TRANSACTION [transaction_mode] [READ ONLY | READ WRITE]

SET SESSION CHARACTERISTICS AS TRANSACTION transaction_mode
[READ ONLY | READ WRITE]
```

where *transaction\_mode* is one of:

```
ISOLATION LEVEL {SERIALIZABLE | REPEATABLE READ | READ
COMMITTED | READ UNCOMMITTED}
```

---

### Description

The `SET TRANSACTION` command sets the characteristics of the current transaction. It has no effect on any subsequent transactions.

The available transaction characteristics are the transaction isolation level and the transaction access mode (read/write or read-only).

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently.

- **READ COMMITTED** — A statement can only see rows committed before it began. This is the default.
- **SERIALIZABLE** — All statements of the current transaction can only see rows committed before the first query or data-modification statement was executed in this transaction.

The SQL standard defines two additional levels, `READ UNCOMMITTED` and `REPEATABLE READ`. In Greenplum Database `READ UNCOMMITTED` is treated as `READ COMMITTED`, while `REPEATABLE READ` is treated as `SERIALIZABLE`.

The transaction isolation level cannot be changed after the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) of a transaction has been executed.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would execute is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

---

### Parameters

#### SESSION CHARACTERISTICS

Sets the default transaction characteristics for subsequent transactions of a session.

**SERIALIZABLE**  
**REPEATABLE READ**  
**READ COMMITTED**  
**READ UNCOMMITTED**

The SQL standard defines four transaction isolation levels: `READ COMMITTED`, `READ UNCOMMITTED`, `SERIALIZABLE`, and `REPEATABLE READ`. The default behavior is that a statement can only see rows committed before it began (`READ COMMITTED`). In Greenplum Database `READ UNCOMMITTED` is treated the same as `READ COMMITTED`. `SERIALIZABLE` is supported the same as `REPEATABLE READ` wherein all statements of the current transaction can only see rows committed before the first statement was executed in the transaction. `SERIALIZABLE` is the strictest transaction isolation. This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. Applications using this level must be prepared to retry transactions due to serialization failures.

**READ WRITE**  
**READ ONLY**

Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would execute is among those listed.

---

## Notes

If `SET TRANSACTION` is executed without a prior `START TRANSACTION` or `BEGIN`, it will appear to have no effect.

It is possible to dispense with `SET TRANSACTION` by instead specifying the desired `transaction_modes` in `BEGIN` or `START TRANSACTION`.

The session default transaction modes can also be set by setting the configuration parameters `default_transaction_isolation` and `default_transaction_read_only`.

---

## Examples

Set the transaction isolation level for the current transaction:

```
BEGIN;
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
```

---

## Compatibility

Both commands are defined in the SQL standard. `SERIALIZABLE` is the default transaction isolation level in the standard. In Greenplum Database the default is `READ COMMITTED`. Because of lack of predicate locking, the `SERIALIZABLE` level is not truly serializable. Essentially, a predicate-locking system prevents phantom reads by restricting what is written, whereas a multi-version concurrency control model (MVCC) as used in Greenplum Database prevents them by restricting what is read.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the Greenplum Database server.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons Greenplum Database allows the commas to be omitted.

[BEGIN](#), [LOCK](#)

---

## SHOW

Shows the value of a system configuration parameter.

---

### Synopsis

```
SHOW configuration_parameter
```

```
SHOW ALL
```

---

### Description

SHOW displays the current settings of Greenplum Database system configuration parameters. You can set these parameters with the SET statement, or by editing the `postgresql.conf` configuration file of the Greenplum Database master. Note that some parameters viewable by SHOW are read-only — their values can be viewed but not set. See the *Greenplum Database Reference Guide* for details.

---

### Parameters

*configuration\_parameter*

The name of a system configuration parameter.

**ALL**

Shows the current value of all configuration parameters.

---

### Examples

Show the current setting of the parameter *search\_path*:

```
SHOW search_path;
```

Show the current setting of all parameters:

```
SHOW ALL;
```

---

### Compatibility

SHOW is a Greenplum Database extension.

---

### See Also

[SET](#), [RESET](#)

---

## START TRANSACTION

Starts a transaction block.

---

### Synopsis

```
START TRANSACTION [SERIALIZABLE | REPEATABLE READ | READ
COMMITTED | READ UNCOMMITTED] [READ WRITE | READ ONLY]
```

---

### Description

`START TRANSACTION` begins a new transaction block. If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if `SET TRANSACTION` was executed. This is the same as the `BEGIN` command.

---

### Parameters

**SERIALIZABLE**  
**REPEATABLE READ**  
**READ COMMITTED**  
**READ UNCOMMITTED**

The SQL standard defines four transaction isolation levels: `READ COMMITTED`, `READ UNCOMMITTED`, `SERIALIZABLE`, and `REPEATABLE READ`. The default behavior is that a statement can only see rows committed before it began (`READ COMMITTED`). In Greenplum Database `READ UNCOMMITTED` is treated the same as `READ COMMITTED`. `SERIALIZABLE` is supported the same as `REPEATABLE READ` wherein all statements of the current transaction can only see rows committed before the first statement was executed in the transaction. `SERIALIZABLE` is the strictest transaction isolation. This level emulates serial transaction execution, as if transactions had been executed one after another, serially, rather than concurrently. Applications using this level must be prepared to retry transactions due to serialization failures.

**READ WRITE**  
**READ ONLY**

Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would execute is among those listed.

---

### Examples

To begin a transaction block:

```
START TRANSACTION;
```

---

## Compatibility

In the standard, it is not necessary to issue `START TRANSACTION` to start a transaction block: any SQL command implicitly begins a block. Greenplum Database behavior can be seen as implicitly issuing a `COMMIT` after each command that does not follow `START TRANSACTION` (or `BEGIN`), and it is therefore often called ‘autocommit’. Other relational database systems may offer an autocommit feature as a convenience.

The SQL standard requires commas between successive *transaction\_modes*, but for historical reasons Greenplum Database allows the commas to be omitted.

See also the compatibility section of [SET TRANSACTION](#).

---

## See Also

[BEGIN](#), [SET TRANSACTION](#)

---

## TRUNCATE

Empties a table of all rows.

---

### Synopsis

```
TRUNCATE [TABLE] name [, ...] [CASCADE | RESTRICT]
```

---

### Description

TRUNCATE quickly removes all rows from a table or set of tables. It has the same effect as an unqualified [DELETE](#) on each table, but since it does not actually scan the tables it is faster. This is most useful on large tables.

---

### Parameters

#### *name*

The name (optionally schema-qualified) of a table to be truncated.

#### CASCADE

Since this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

#### RESTRICT

Since this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

---

### Notes

Only the owner of a table may TRUNCATE it.

TRUNCATE will not run any user-defined ON DELETE triggers that might exist for the tables.

TRUNCATE will not truncate any tables that inherit from the named table. Only the named table is truncated, not its child tables.

TRUNCATE will not truncate any sub-tables of a partitioned table. If you specify a sub-table of a partitioned table, TRUNCATE will not remove rows from the sub-table and its child tables.

---

### Examples

Empty the table films:

```
TRUNCATE films;
```

---

### Compatibility

There is no TRUNCATE command in the SQL standard.

---

## See Also

[DELETE, DROP TABLE](#)

---

## UPDATE

Updates rows of a table.

---

### Synopsis

```
UPDATE [ONLY] table [[AS] alias]
  SET {column = {expression | DEFAULT} |
      (column [, ...]) = ({expression | DEFAULT} [, ...])} [, ...]
  [FROM fromlist]
  [WHERE condition | WHERE CURRENT OF cursor_name ]
```

---

### Description

UPDATE changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the SET clause; columns not explicitly modified retain their previous values.

By default, UPDATE will update rows in the specified table and all its subtables. If you wish to only update the specific table mentioned, you must use the ONLY clause.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the FROM clause. Which technique is more appropriate depends on the specific circumstances.

If the WHERE CURRENT OF clause is specified, the row that is updated is the one most recently fetched from the specified cursor.

You must have the UPDATE privilege on the table to update it, as well as the SELECT privilege to any table whose values are read in the expressions or condition.

### Outputs

On successful completion, an UPDATE command returns a command tag of the form:

```
UPDATE count
```

Where count is the number of rows updated. If count is 0, no rows matched the condition (this is not considered an error).

---

### Parameters

#### ONLY

If specified, update rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

#### *table*

The name (optionally schema-qualified) of an existing table.

***alias***

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `UPDATE foo AS f`, the remainder of the `UPDATE` statement must refer to this table as `f` not `foo`.

***column***

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column.

***expression***

An expression to assign to the column. The expression may use the old values of this and other columns in the table.

**DEFAULT**

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it).

***fromlist***

A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition and the update expressions. This is similar to the list of tables that can be specified in the `FROM` clause of a `SELECT` statement. Note that the target table must not appear in the *fromlist*, unless you intend a self-join (in which case it must appear with an *alias* in the *fromlist*).

***condition***

An expression that returns a value of type boolean. Only rows for which this expression returns true will be updated.

***cursor\_name***

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be updated is the one most recently fetched from the cursor. The cursor must be a simple (non-join, non-aggregate) query on the `UPDATE` command target table. See [DECLARE](#) for more information about creating cursors.

`WHERE CURRENT OF` cannot be specified together with a Boolean condition.

***output\_expression***

An expression to be computed and returned by the `UPDATE` command after each row is updated. The expression may use any column names of the table or table(s) listed in `FROM`. Write `*` to return all columns.

***output\_name***

A name to use for a returned column.

---

**Notes**

`SET` is not allowed on the Greenplum distribution key columns of a table.

When a `FROM` clause is present, what essentially happens is that the target table is joined to the tables mentioned in the from list, and each output row of the join represents an update operation for the target table. When using `FROM` you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row should not join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

Execution of `INSERT`, `UPDATE` and `DELETE` commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, these commands must be executed on the root partitioned table, the table created with the `CREATE TABLE` command.

---

## Examples

Change the word *Drama* to *Dramatic* in the column *kind* of the table *films*:

```
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table *weather*:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi =
temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2006-07-03';
```

Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1,
temp_lo+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2006-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the `FROM` clause syntax (assuming both tables being joined are distributed in Greenplum Database on the *id* column):

```
UPDATE employees SET sales_count = sales_count + 1 FROM
accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.id;
```

Perform the same operation, using a sub-select in the `WHERE` clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
(SELECT id FROM accounts WHERE name = 'Acme Corporation');
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints.

```
BEGIN;
-- other operations
SAVEPOINT sp1;
```

```

INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau
Lafite 2003';
-- continue with other operations, and eventually
COMMIT;

```

---

## Compatibility

This command conforms to the SQL standard, except that the `FROM` clause is a Greenplum Database extension.

According to the standard, the column-list syntax should allow a list of columns to be assigned from a single row-valued expression, such as a sub-select:

```

UPDATE accounts SET (contact_last_name, contact_first_name) =
    (SELECT last_name, first_name FROM salesmen
     WHERE salesmen.id = accounts.sales_id);

```

This is not currently implemented — the source must be a list of independent expressions.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how Greenplum Database interprets `FROM`. Be careful when porting applications that use this extension.

---

## See Also

[DECLARE](#), [DELETE](#), [SELECT](#), [INSERT](#)

---

## VACUUM

Garbage-collects and optionally analyzes a database.

---

### Synopsis

```
VACUUM [FULL] [FREEZE] [VERBOSE] [table]
VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE
      [table [(column [, ...] )]]
```

---

### Description

VACUUM reclaims storage occupied by deleted tuples. In normal Greenplum Database operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present on disk until a VACUUM is done. Therefore it is necessary to do VACUUM periodically, especially on frequently-updated tables.

With no parameter, VACUUM processes every table in the current database. With a parameter, VACUUM processes only that table.

VACUUM ANALYZE performs a VACUUM and then an ANALYZE for each selected table. This is a handy combination form for routine maintenance scripts. See [ANALYZE](#) for more details about its processing.

Plain VACUUM (without FULL) simply reclaims space and makes it available for re-use. With heap tables, this form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained.

VACUUM FULL does more extensive processing, including moving of tuples across blocks to try to compact the table to the minimum number of disk blocks. This form is much slower and requires an exclusive lock on each table while it is being processed.

With append-optimized tables, VACUUM compacts a table by first vacuuming the indexes, then compacting each segment file in turn, and finally vacuuming auxiliary relations and updating statistics. On each segment, visible rows are copied from the current segment file to a new segment file, and then the current segment file is scheduled to be dropped and the new segment file is made available. Plain VACUUM of an append-optimized table allows scans, inserts, deletes, and updates of the table while a segment file is compacted. VACUUM FULL acquires an exclusive lock and disallows inserts, updates and deletes, but SELECT statements can be executed during most of the compaction process. When all visible rows have been copied to the new segment file, the table is locked briefly while the new segment is made available and the old segment is set to be dropped.

### Outputs

When VERBOSE is specified, VACUUM emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

---

## Parameters

**FULL**

Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table.

**Warning:** A `VACUUM FULL` is not recommended in Greenplum Database. See the “Notes” section.

**FREEZE**

Specifying `FREEZE` is equivalent to performing `VACUUM` with the `vacuum_freeze_min_age` server configuration parameter set to zero. The `FREEZE` option is deprecated and will be removed in a future release. Set the parameter in the master `postgresql.conf` file instead.

**VERBOSE**

Prints a detailed vacuum activity report for each table.

**ANALYZE**

Updates statistics used by the planner to determine the most efficient way to execute a query.

***table***

The name (optionally schema-qualified) of a specific table to vacuum. Defaults to all tables in the current database.

***column***

The name of a specific column to analyze. Defaults to all columns.

---

## Notes

`VACUUM` cannot be executed inside a transaction block.

Greenplum recommends that active production databases be vacuumed frequently (at least nightly), in order to remove expired rows. After adding or deleting a large number of rows, it may be a good idea to issue a `VACUUM ANALYZE` command for the affected table. This will update the system catalogs with the results of all recent changes, and allow the Greenplum query planner to make better choices in planning queries.

**Important:** Regular PostgreSQL has a separate optional server process called the *autovacuum daemon*, whose purpose is to automate the execution of `VACUUM` and `ANALYZE` commands. This feature is currently disabled in Greenplum Database.

`VACUUM` causes a substantial increase in I/O traffic, which can cause poor performance for other active sessions. Therefore, it is advisable to vacuum the database at low usage times.

For heap tables, expired rows are held in what is called the *free space map*. The free space map must be sized large enough to cover the dead rows of all heap tables in your database. If not sized large enough, space occupied by dead rows that overflow the free space map cannot be reclaimed by a regular `VACUUM` command.

A `VACUUM FULL` will reclaim all expired row space, but is a very expensive operation and may take an unacceptably long time to finish on large, distributed Greenplum Database tables. If you do get into a situation where the free space map has overflowed, it may be more timely to recreate the table with a `CREATE TABLE AS` statement and drop the old table. A `VACUUM FULL` is not recommended in Greenplum Database.

Size the free space map appropriately. You configure the free space map using the following server configuration parameters:

```
max_fsm_pages
max_fsm_relations
```

For append-optimized tables, `VACUUM` requires enough available disk space to accommodate the new segment file during the `VACUUM` process. If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` Greenplum Database server configuration parameter. `VACUUM FULL` ignores the threshold and rewrites the segment file regardless of the ratio. `VACUUM` can be disabled for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter. See [Chapter 8, “Server Configuration Parameters”](#) for more about server configuration parameters.

If a concurrent serializable transaction is detected when an append-optimized table is being vacuumed, the current and subsequent segment files are not compacted. If a segment file has been compacted but a concurrent serializable transaction is detected in the transaction that drops the original segment file, the drop is skipped. This could leave one or two segment files in an “awaiting drop” state after the vacuum has completed.

For more information about concurrency control in Greenplum Database, see “Routine System Maintenance Tasks” in *Greenplum Database System Administrator Guide*.

---

## Examples

Vacuum all tables in the current database:

```
VACUUM;
```

Vacuum a specific table only:

```
VACUUM mytable;
```

Vacuum all tables in the current database and collect statistics for the query planner:

```
VACUUM ANALYZE;
```

---

## Compatibility

There is no `VACUUM` statement in the SQL standard.

---

## See Also

[ANALYZE](#)

---

## VALUES

Computes a set of rows.

---

### Synopsis

```
VALUES ( expression [, ...] ) [, ...]
[ORDER BY sort_expression [ASC | DESC | USING operator] [, ...]]
[LIMIT {count | ALL}] [OFFSET start]
```

---

### Description

VALUES computes a row value or set of row values specified by value expressions. It is most commonly used to generate a ‘constant table’ within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table’s columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for UNION.

Within larger commands, VALUES is syntactically allowed anywhere that SELECT is. Because it is treated like a SELECT by the grammar, it is possible to use the ORDER BY, LIMIT, and OFFSET clauses with a VALUES command.

---

### Parameters

#### *expression*

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a VALUES list appearing at the top level of an INSERT, an expression can be replaced by DEFAULT to indicate that the destination column’s default value should be inserted. DEFAULT cannot be used when VALUES appears in other contexts.

#### *sort\_expression*

An expression or integer constant indicating how to sort the result rows. This expression may refer to the columns of the VALUES result as *column1*, *column2*, etc. For more details see [“The ORDER BY Clause”](#) on page 287.

#### *operator*

A sorting operator. For details see [“The ORDER BY Clause”](#) on page 287.

#### **LIMIT** *count* **OFFSET** *start*

The maximum number of rows to return. For details see [“The LIMIT Clause”](#) on page 288.

---

## Notes

VALUES lists with very large numbers of rows should be avoided, as you may encounter out-of-memory failures or poor performance. VALUES appearing within INSERT is a special case (because the desired column types are known from the INSERT's target table, and need not be inferred by scanning the VALUES list), so it can handle larger lists than are practical in other contexts.

---

## Examples

A bare VALUES command:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It is effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, VALUES is used within a larger SQL command. The most common use is in INSERT:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of INSERT, entries of a VALUES list can be DEFAULT to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82
minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

VALUES can also be used where a sub-SELECT might be written, for example in a FROM clause:

```
SELECT f.* FROM films f, (VALUES('MGM', 'Horror'), ('UA',
'Sci-Fi')) AS t (studio, kind) WHERE f.studio = t.studio AND
f.kind = t.kind;
UPDATE employees SET salary = salary * v.increase FROM
(VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno,
target, increase) WHERE employees.depno = v.depno AND
employees.sales >= v.target;
```

Note that an AS clause is required when VALUES is used in a FROM clause, just as is true for SELECT. It is not required that the AS clause specify names for all the columns, but it is good practice to do so. The default column names for VALUES are column1, column2, etc. in Greenplum Database, but these names might be different in other database systems.

When `VALUES` is used in `INSERT`, the values are all automatically coerced to the data type of the corresponding destination column. When it is used in other contexts, it may be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines WHERE ip_address IN
  (VALUES ('192.168.0.1'::inet), ('192.168.0.10'),
   ('192.168.1.43'));
```

**Note:** For simple `IN` tests, it is better to rely on the list-of-scalars form of `IN` than to write a `VALUES` query as shown above. The list of scalars method requires less writing and is often more efficient.

---

## Compatibility

`VALUES` conforms to the SQL standard, except that `LIMIT` and `OFFSET` are Greenplum Database extensions.

---

[INSERT](#), [SELECT](#)

## 2. SQL 2008 Optional Feature Compliance

The following table lists the features described in the 2008 SQL standard. Features that are supported in Greenplum Database are marked as YES in the ‘Supported’ column, features that are not implemented are marked as NO.

For information about Greenplum features and SQL compliance, see the *Greenplum Database Database Administrator Guide*.

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
B011	Embedded Ada	NO	
B012	Embedded C	NO	Due to issues with PostgreSQL ecpg
B013	Embedded COBOL	NO	
B014	Embedded Fortran	NO	
B015	Embedded MUMPS	NO	
B016	Embedded Pascal	NO	
B017	Embedded PL/I	NO	
B021	Direct SQL	YES	
B031	Basic dynamic SQL	NO	
B032	Extended dynamic SQL	NO	
B033	Untyped SQL-invoked function arguments	NO	
B034	Dynamic specification of cursor attributes	NO	
B035	Non-extended descriptor names	NO	
B041	Extensions to embedded SQL exception declarations	NO	
B051	Enhanced execution rights	NO	
B111	Module language Ada	NO	
B112	Module language C	NO	
B113	Module language COBOL	NO	
B114	Module language Fortran	NO	
B115	Module language MUMPS	NO	
B116	Module language Pascal	NO	
B117	Module language PL/I	NO	
B121	Routine language Ada	NO	
B122	Routine language C	NO	
B123	Routine language COBOL	NO	
B124	Routine language Fortran	NO	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
B125	Routine language MUMPS	NO	
B126	Routine language Pascal	NO	
B127	Routine language PL/I	NO	
B128	Routine language SQL	NO	
<b>E011</b>	<b>Numeric data types</b>	<b>YES</b>	
E011-01	INTEGER and SMALLINT data types	YES	
E011-02	DOUBLE PRECISION and FLOAT data types	YES	
E011-03	DECIMAL and NUMERIC data types	YES	
E011-04	Arithmetic operators	YES	
E011-05	Numeric comparison	YES	
E011-06	Implicit casting among the numeric data types	YES	
<b>E021</b>	<b>Character data types</b>	<b>YES</b>	
E021-01	CHARACTER data type	YES	
E021-02	CHARACTER VARYING data type	YES	
E021-03	Character literals	YES	
E021-04	CHARACTER_LENGTH function	YES	Trims trailing spaces from CHARACTER values before counting
E021-05	OCTET_LENGTH function	YES	
E021-06	SUBSTRING function	YES	
E021-07	Character concatenation	YES	
E021-08	UPPER and LOWER functions	YES	
E021-09	TRIM function	YES	
E021-10	Implicit casting among the character string types	YES	
E021-11	POSITION function	YES	
E021-12	Character comparison	YES	
<b>E031</b>	<b>Identifiers</b>	<b>YES</b>	
E031-01	Delimited identifiers	YES	
E031-02	Lower case identifiers	YES	
E031-03	Trailing underscore	YES	
<b>E051</b>	<b>Basic query specification</b>	<b>YES</b>	
E051-01	SELECT DISTINCT	YES	
E051-02	GROUP BY clause	YES	
E051-03	GROUP BY can contain columns not in SELECT list	YES	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
E051-04	SELECT list items can be renamed	YES	
E051-05	HAVING clause	YES	
E051-06	Qualified * in SELECT list	YES	
E051-07	Correlation names in the FROM clause	YES	
E051-08	Rename columns in the FROM clause	YES	
<b>E061</b>	<b>Basic predicates and search conditions</b>	<b>YES</b>	
E061-01	Comparison predicate	YES	
E061-02	BETWEEN predicate	YES	
E061-03	IN predicate with list of values	YES	
E061-04	LIKE predicate	YES	
E061-05	LIKE predicate ESCAPE clause	YES	
E061-06	NULL predicate	YES	
E061-07	Quantified comparison predicate	YES	Not all uses work in Greenplum
E061-08	EXISTS predicate	YES	
E061-09	Subqueries in comparison predicate	YES	
E061-11	Subqueries in IN predicate	YES	
E061-12	Subqueries in quantified comparison predicate	YES	
E061-13	Correlated subqueries	YES	
E061-14	Search condition	YES	
<b>E071</b>	<b>Basic query expressions</b>	<b>YES</b>	
E071-01	UNION DISTINCT table operator	YES	
E071-02	UNION ALL table operator	YES	
E071-03	EXCEPT DISTINCT table operator	YES	
E071-05	Columns combined via table operators need not have exactly the same data type	YES	
E071-06	Table operators in subqueries	YES	
<b>E081</b>	<b>Basic Privileges</b>	<b>NO</b>	Partial sub-feature support
E081-01	SELECT privilege	YES	
E081-02	DELETE privilege	YES	
E081-03	INSERT privilege at the table level	YES	
E081-04	UPDATE privilege at the table level	YES	
E081-05	UPDATE privilege at the column level	NO	
E081-06	REFERENCES privilege at the table level	NO	
E081-07	REFERENCES privilege at the column level	NO	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
E081-08	WITH GRANT OPTION	YES	
E081-09	USAGE privilege	YES	
E081-10	EXECUTE privilege	YES	
<b>E091</b>	<b>Set Functions</b>	<b>YES</b>	
E091-01	AVG	YES	
E091-02	COUNT	YES	
E091-03	MAX	YES	
E091-04	MIN	YES	
E091-05	SUM	YES	
E091-06	ALL quantifier	YES	
E091-07	DISTINCT quantifier	YES	
<b>E101</b>	<b>Basic data manipulation</b>	<b>YES</b>	
E101-01	INSERT statement	YES	
E101-03	Searched UPDATE statement	YES	
E101-04	Searched DELETE statement	YES	
E111	Single row SELECT statement	YES	
<b>E121</b>	<b>Basic cursor support</b>	<b>YES</b>	
E121-01	DECLARE CURSOR	YES	
E121-02	ORDER BY columns need not be in select list	YES	
E121-03	Value expressions in ORDER BY clause	YES	
E121-04	OPEN statement	YES	
E121-06	Positioned UPDATE statement	NO	
E121-07	Positioned DELETE statement	NO	
E121-08	CLOSE statement	YES	
E121-10	FETCH statement implicit NEXT	YES	
E121-17	WITH HOLD cursors	YES	
E131	Null value support	YES	
<b>E141</b>	<b>Basic integrity constraints</b>	<b>YES</b>	
E141-01	NOT NULL constraints	YES	
E141-02	UNIQUE constraints of NOT NULL columns	YES	Must be the same as or a superset of the Greenplum distribution key
E141-03	PRIMARY KEY constraints	YES	Must be the same as or a superset of the Greenplum distribution key

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
E141-04	Basic FOREIGN KEY constraint with the NO ACTION default for both referential delete action and referential update action	NO	Foreign keys can be declared but are not enforced in Greenplum
E141-06	CHECK constraints	YES	
E141-07	Column defaults	YES	
E141-08	NOT NULL inferred on PRIMARY KEY	YES	
E141-10	Names in a foreign key can be specified in any order	YES	
<b>E151</b>	<b>Transaction support</b>	<b>YES</b>	
E151-01	COMMIT statement	YES	
E151-02	ROLLBACK statement	YES	
<b>E152</b>	<b>Basic SET TRANSACTION statement</b>	<b>YES</b>	
E152-01	ISOLATION LEVEL SERIALIZABLE clause	YES	
E152-02	READ ONLY and READ WRITE clauses	YES	
E153	Updatable queries with subqueries	NO	
E161	SQL comments using leading double minus	YES	
E171	SQLSTATE support	YES	
E182	Module language	NO	
<b>F021</b>	<b>Basic information schema</b>	<b>YES</b>	
F021-01	COLUMNS view	YES	
F021-02	TABLES view	YES	
F021-03	VIEWS view	YES	
F021-04	TABLE_CONSTRAINTS view	YES	
F021-05	REFERENTIAL_CONSTRAINTS view	YES	
F021-06	CHECK_CONSTRAINTS view	YES	
<b>F031</b>	<b>Basic schema manipulation</b>	<b>YES</b>	
F031-01	CREATE TABLE statement to create persistent base tables	YES	
F031-02	CREATE VIEW statement	YES	
F031-03	GRANT statement	YES	
F031-04	ALTER TABLE statement: ADD COLUMN clause	YES	
F031-13	DROP TABLE statement: RESTRICT clause	YES	
F031-16	DROP VIEW statement: RESTRICT clause	YES	
F031-19	REVOKE statement: RESTRICT clause	YES	
F032	CASCADE drop behavior	YES	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
F033	ALTER TABLE statement: DROP COLUMN clause	YES	
<b>F034</b>	<b>Extended REVOKE statement</b>	<b>YES</b>	
F034-01	REVOKE statement performed by other than the owner of a schema object	YES	
F034-02	REVOKE statement: GRANT OPTION FOR clause	YES	
F034-03	REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION	YES	
<b>F041</b>	<b>Basic joined table</b>	<b>YES</b>	
F041-01	Inner join (but not necessarily the INNER keyword)	YES	
F041-02	INNER keyword	YES	
F041-03	LEFT OUTER JOIN	YES	
F041-04	RIGHT OUTER JOIN	YES	
F041-05	Outer joins can be nested	YES	
F041-07	The inner table in a left or right outer join can also be used in an inner join	YES	
F041-08	All comparison operators are supported (rather than just =)	YES	
F051	Basic date and time	YES	
F051-01	DATE data type (including support of DATE literal)	YES	
F051-02	TIME data type (including support of TIME literal) with fractional seconds precision of at least 0	YES	
F051-03	TIMESTAMP data type (including support of TIMESTAMP literal) with fractional seconds precision of at least 0 and 6	YES	
F051-04	Comparison predicate on DATE, TIME, and TIMESTAMP data types	YES	
F051-05	Explicit CAST between datetime types and character string types	YES	
F051-06	CURRENT_DATE	YES	
F051-07	LOCALTIME	YES	
F051-08	LOCALTIMESTAMP	YES	
F052	Intervals and datetime arithmetic	YES	
F053	OVERLAPS predicate	YES	
F081	UNION and EXCEPT in views	YES	
<b>F111</b>	<b>Isolation levels other than SERIALIZABLE</b>	<b>YES</b>	
F111-01	READ UNCOMMITTED isolation level	NO	Can be declared but is treated as a synonym for READ COMMITTED

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
F111-02	READ COMMITTED isolation level	YES	Can be declared but is treated as a synonym for SERIALIZABLE
F111-03	REPEATABLE READ isolation level	NO	
F121	Basic diagnostics management	NO	
F122	Enhanced diagnostics management	NO	
F123	All diagnostics	NO	
<b>F131-</b>	<b>Grouped operations</b>	<b>YES</b>	
F131-01	WHERE, GROUP BY, and HAVING clauses supported in queries with grouped views	YES	
F131-02	Multiple tables supported in queries with grouped views	YES	
F131-03	Set functions supported in queries with grouped views	YES	
F131-04	Subqueries with GROUP BY and HAVING clauses and grouped views	YES	
F131-05	Single row SELECT with GROUP BY and HAVING clauses and grouped views	YES	
F171	Multiple schemas per user	YES	
F181	Multiple module support	NO	
F191	Referential delete actions	NO	
F200	TRUNCATE TABLE statement	YES	
F201	CAST function	YES	
F202	TRUNCATE TABLE: identity column restart option	NO	
F221	Explicit defaults	YES	
F222	INSERT statement: DEFAULT VALUES clause	YES	
<b>F231</b>	<b>Privilege tables</b>	<b>YES</b>	
F231-01	TABLE_PRIVILEGES view	YES	
F231-02	COLUMN_PRIVILEGES view	YES	
F231-03	USAGE_PRIVILEGES view	YES	
F251	Domain support		
<b>F261</b>	<b>CASE expression</b>	<b>YES</b>	
F261-01	Simple CASE	YES	
F261-02	Searched CASE	YES	
F261-03	NULLIF	YES	
F261-04	COALESCE	YES	
F262	Extended CASE expression	NO	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
F263	Comma-separated predicates in simple CASE expression	NO	
F271	Compound character literals	YES	
F281	LIKE enhancements	YES	
F291	UNIQUE predicate	NO	
F301	CORRESPONDING in query expressions	NO	
<b>F302</b>	<b>INTERSECT table operator</b>	<b>YES</b>	
F302-01	INTERSECT DISTINCT table operator	YES	
F302-02	INTERSECT ALL table operator	YES	
F304	EXCEPT ALL table operator		
<b>F311</b>	<b>Schema definition statement</b>	<b>YES</b>	<b>Partial sub-feature support</b>
F311-01	CREATE SCHEMA	YES	
F311-02	CREATE TABLE for persistent base tables	YES	
F311-03	CREATE VIEW	YES	
F311-04	CREATE VIEW: WITH CHECK OPTION	NO	
F311-05	GRANT statement	YES	
F312	MERGE statement	NO	
F313	Enhanced MERGE statement	NO	
F321	User authorization	YES	
F341	Usage Tables	NO	
F361	Subprogram support	YES	
<b>F381</b>	<b>Extended schema manipulation</b>	<b>YES</b>	
F381-01	ALTER TABLE statement: ALTER COLUMN clause		Some limitations on altering distribution key columns
F381-02	ALTER TABLE statement: ADD CONSTRAINT clause		
F381-03	ALTER TABLE statement: DROP CONSTRAINT clause		
F382	Alter column data type	YES	Some limitations on altering distribution key columns
F391	Long identifiers	YES	
F392	Unicode escapes in identifiers	NO	
F393	Unicode escapes in literals	NO	
F394	Optional normal form specification	NO	
<b>F401</b>	<b>Extended joined table</b>	<b>YES</b>	
F401-01	NATURAL JOIN	YES	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
F401-02	FULL OUTER JOIN	YES	
F401-04	CROSS JOIN	YES	
F402	Named column joins for LOBs, arrays, and multisets	NO	
F403	Partitioned joined tables	NO	
F411	Time zone specification	YES	Differences regarding literal interpretation
F421	National character	YES	
<b>F431</b>	<b>Read-only scrollable cursors</b>	<b>YES</b>	<b>Forward scrolling only</b>
01	FETCH with explicit NEXT	YES	
02	FETCH FIRST	NO	
03	FETCH LAST	YES	
04	FETCH PRIOR	NO	
05	FETCH ABSOLUTE	NO	
06	FETCH RELATIVE	NO	
F441	Extended set function support	YES	
F442	Mixed column references in set functions	YES	
F451	Character set definition	NO	
F461	Named character sets	NO	
F471	Scalar subquery values	YES	
F481	Expanded NULL predicate	YES	
F491	Constraint management	YES	
<b>F501</b>	<b>Features and conformance views</b>	<b>YES</b>	
F501-01	SQL_FEATURES view	YES	
F501-02	SQL_SIZING view	YES	
F501-03	SQL_LANGUAGES view	YES	
<b>F502</b>	<b>Enhanced documentation tables</b>	<b>YES</b>	
F502-01	SQL_SIZING_PROFILES view	YES	
F502-02	SQL_IMPLEMENTATION_INFO view	YES	
F502-03	SQL_PACKAGES view	YES	
F521	Assertions	NO	
F531	Temporary tables	YES	Non-standard form
F555	Enhanced seconds precision	YES	
F561	Full value expressions	YES	
F571	Truth value tests	YES	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
F591	Derived tables	YES	
F611	Indicator data types	YES	
F641	Row and table constructors	NO	
F651	Catalog name qualifiers	YES	
F661	Simple tables	NO	
F671	Subqueries in CHECK	NO	Intentionally omitted
F672	Retrospective check constraints	YES	
F690	Collation support	NO	
F692	Enhanced collation support	NO	
F693	SQL-session and client module collations	NO	
F695	Translation support	NO	
F696	Additional translation documentation	NO	
F701	Referential update actions	NO	
F711	ALTER domain	YES	
F721	Deferrable constraints	NO	
F731	INSERT column privileges	NO	
F741	Referential MATCH types	NO	No partial match
F751	View CHECK enhancements	NO	
F761	Session management	YES	
F762	CURRENT_CATALOG	NO	
F763	CURRENT_SCHEMA	NO	
F771	Connection management	YES	
F781	Self-referencing operations	YES	
F791	Insensitive cursors	YES	
F801	Full set function	YES	
F812	Basic flagging	NO	
F813	Extended flagging	NO	
F831	Full cursor update	NO	
F841	LIKE_REGEX predicate	NO	Non-standard syntax for regex
F842	OCCURENCES_REGEX function	NO	
F843	POSITION_REGEX function	NO	
F844	SUBSTRING_REGEX function	NO	
F845	TRANSLATE_REGEX function	NO	
F846	Octet support in regular expression operators	NO	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
F847	Nonconstant regular expressions	NO	
F850	Top-level ORDER BY clause in <i>query expression</i>	YES	
F851	Top-level ORDER BY clause in subqueries	NO	
F852	Top-level ORDER BY clause in views	NO	
F855	Nested ORDER BY clause in <i>query expression</i>	NO	
F856	Nested FETCH FIRST clause in <i>query expression</i>	NO	
F857	Top-level FETCH FIRST clause in <i>query expression</i>	NO	
F858	FETCH FIRST clause in subqueries	NO	
F859	Top-level FETCH FIRST clause in views	NO	
F860	FETCH FIRST ROW <i>count</i> in FETCH FIRST clause	NO	
F861	Top-level RESULT OFFSET clause in <i>query expression</i>	NO	
F862	RESULT OFFSET clause in subqueries	NO	
F863	Nested RESULT OFFSET clause in <i>query expression</i>	NO	
F864	Top-level RESULT OFFSET clause in views	NO	
F865	OFFSET ROW <i>count</i> in RESULT OFFSET clause	NO	
S011	Distinct data types	NO	
S023	Basic structured types	NO	
S024	Enhanced structured types	NO	
S025	Final structured types	NO	
S026	Self-referencing structured types	NO	
S027	Create method by specific method name	NO	
S028	Permutable UDT options list	NO	
S041	Basic reference types	NO	
S043	Enhanced reference types	NO	
S051	Create table of type	NO	
S071	SQL paths in function and type name resolution	YES	
<b>S091</b>	<b>Basic array support</b>	<b>NO</b>	<b>Greenplum has arrays, but is not fully standards compliant</b>
S091-01	Arrays of built-in data types	NO	Partially compliant
S091-02	Arrays of distinct types	NO	
S091-03	Array expressions	NO	
S092	Arrays of user-defined types	NO	
S094	Arrays of reference types	NO	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
S095	Array constructors by query	NO	
S096	Optional array bounds	NO	
S097	Array element assignment	NO	
S098	ARRAY_AGG	Partially	<p><b>Supported:</b> Using array_agg without a window specification; for example</p> <pre>SELECT array_agg(x) FROM ...  SELECT array_agg (x order by y) FROM ...</pre> <p><b>Not supported:</b> Using array_agg as an aggregate derived window function; for example</p> <pre>SELECT array_agg(x) over (ORDER BY y) FROM ...  SELECT array_agg(x order by y) over (PARTITION BY z) FROM ...  SELECT array_agg(x order by y) over (ORDER BY z) FROM ...</pre>
S111	ONLY in query expressions	YES	
S151	Type predicate	NO	
S161	Subtype treatment	NO	
S162	Subtype treatment for references	NO	
S201	SQL-invoked routines on arrays	NO	Functions can be passed Greenplum array types
S202	SQL-invoked routines on multisets	NO	
S211	User-defined cast functions	YES	
S231	Structured type locators	NO	
S232	Array locators	NO	
S233	Multiset locators	NO	
S241	Transform functions	NO	
S242	Alter transform statement	NO	
S251	User-defined orderings	NO	
S261	Specific type method	NO	
S271	Basic multiset support	NO	
S272	Multisets of user-defined types	NO	
S274	Multisets of reference types	NO	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
S275	Advanced multiset support	NO	
S281	Nested collection types	NO	
S291	Unique constraint on entire row	NO	
S301	Enhanced UNNEST	NO	
S401	Distinct types based on array types	NO	
S402	Distinct types based on distinct types	NO	
S403	MAX_CARDINALITY	NO	
S404	TRIM_ARRAY	NO	
T011	Timestamp in Information Schema	NO	
T021	BINARY and VARBINARY data types	NO	
T022	Advanced support for BINARY and VARBINARY data types	NO	
T023	Compound binary literal	NO	
T024	Spaces in binary literals	NO	
T031	BOOLEAN data type	YES	
T041	Basic LOB data type support	NO	
T042	Extended LOB data type support	NO	
T043	Multiplier T	NO	
T044	Multiplier P	NO	
T051	Row types	NO	
T052	MAX and MIN for row types	NO	
T053	Explicit aliases for all-fields reference	NO	
T061	UCS support	NO	
T071	BIGINT data type	YES	
T101	Enhanced nullability determination	NO	
T111	Updatable joins, unions, and columns	NO	
T121	WITH (excluding RECURSIVE) in query expression	NO	
T122	WITH (excluding RECURSIVE) in subquery	NO	
T131	Recursive query	NO	
T132	Recursive query in subquery	NO	
T141	SIMILAR predicate	YES	
T151	DISTINCT predicate	YES	
T152	DISTINCT predicate with negation	NO	
T171	LIKE clause in table definition	YES	

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
T172	AS subquery clause in table definition	YES	
T173	Extended LIKE clause in table definition	YES	
T174	Identity columns	NO	
T175	Generated columns	NO	
T176	Sequence generator support	NO	
T177	Sequence generator support: simple restart option	NO	
T178	Identity columns: simple restart option	NO	
T191	Referential action RESTRICT	NO	
T201	Comparable data types for referential constraints	NO	
<b>T211</b>	<b>Basic trigger capability</b>	<b>NO</b>	Intentionally omitted
T211-01	Triggers activated on UPDATE, INSERT, or DELETE of one base table	NO	
T211-02	BEFORE triggers	NO	
T211-03	AFTER triggers	NO	
T211-04	FOR EACH ROW triggers	NO	
T211-05	Ability to specify a search condition that must be true before the trigger is invoked	NO	
T211-06	Support for run-time rules for the interaction of triggers and constraints	NO	
T211-07	TRIGGER privilege	YES	
T211-08	Multiple triggers for the same event are executed in the order in which they were created in the catalog	NO	
T212	Enhanced trigger capability	NO	
T213	INSTEAD OF triggers	NO	
T231	Sensitive cursors	YES	
T241	START TRANSACTION statement	YES	
T251	SET TRANSACTION statement: LOCAL option	NO	
T261	Chained transactions	NO	
T271	Savepoints	YES	
T272	Enhanced savepoint management	NO	
T281	SELECT privilege with column granularity	NO	
T285	Enhanced derived column names	NO	
T301	Functional dependencies	NO	
T312	OVERLAY function	YES	
<b>T321</b>	<b>Basic SQL-invoked routines</b>	<b>NO</b>	<b>Partial support</b>

**Table 2.1** SQL 2008 Optional Feature Compliance Details

ID	Feature	Supported	Comments
T321-01	User-defined functions with no overloading	YES	
T321-02	User-defined stored procedures with no overloading	NO	
T321-03	Function invocation	YES	
T321-04	CALL statement	NO	
T321-05	RETURN statement	NO	
T321-06	ROUTINES view	YES	
T321-07	PARAMETERS view	YES	
T322	Overloading of SQL-invoked functions and procedures	YES	
T323	Explicit security for external routines	YES	
T324	Explicit security for SQL routines	NO	
T325	Qualified SQL parameter references	NO	
T326	Table functions	NO	
T331	Basic roles	NO	
T332	Extended roles	NO	
T351	Bracketed SQL comments ( <code>/* . . . */</code> comments)	YES	
T431	Extended grouping capabilities	NO	
T432	Nested and concatenated <code>GROUPING SETS</code>	NO	
T433	Multiargument <code>GROUPING</code> function	NO	
T434	<code>GROUP BY DISTINCT</code>	NO	
T441	<code>ABS</code> and <code>MOD</code> functions	YES	
T461	Symmetric <code>BETWEEN</code> predicate	YES	
T471	Result sets return value	NO	
T491	<code>LATERAL</code> derived table	NO	
T501	Enhanced <code>EXISTS</code> predicate	NO	
T511	Transaction counts	NO

# 3. System Catalog Reference

This reference describes the Greenplum Database system catalog tables and views. System tables prefixed with *gp\_* relate to the parallel features of Greenplum Database. Tables prefixed with *pg\_* are either standard PostgreSQL system catalog tables supported in Greenplum Database, or are related to features Greenplum that provides to enhance PostgreSQL for data warehousing workloads. Note that the global system catalog for Greenplum Database resides on the master instance.

---

## System Tables

- [gp\\_configuration](#) (Deprecated. See [gp\\_segment\\_configuration](#).)

- [pg\\_trigger](#)
- [pg\\_type](#)
- [pg\\_user\\_mapping](#) (not supported in 4.3)
- [pg\\_window](#)

### System Views

Greenplum Database provides the following system views not available in PostgreSQL.

- [gp\\_distributed\\_log](#)
- [gp\\_distributed\\_xacts](#)
- [gp\\_pgdatabase](#)
- [gp\\_resqueue\\_status](#)
- [gp\\_transaction\\_log](#)
- [gpexpand.expansion\\_progress](#)
- [pg\\_max\\_external\\_files](#) (shows number of external table files allowed per segment host when using the file protocol)
- [pg\\_partition\\_columns](#)
- [pg\\_partition\\_templates](#)
- [pg\\_partitions](#)
- [pg\\_stat\\_activity](#)
- [pg\\_stat\\_replication](#)
- [pg\\_resqueue\\_attributes](#)
- [pg\\_resqueue\\_status](#) (Deprecated. Use [gp\\_toolkit.gp\\_resqueue\\_status](#).)
- [pg\\_stat\\_resqueues](#)
- [pg\\_user\\_mappings](#) (not supported)

For more information about the standard system views supported in PostgreSQL and Greenplum Database, see the following sections of the PostgreSQL documentation:

- [System Views](#)
- [Statistics Collector Views](#)
- [The Information Schema](#)

## gp\_configuration\_history

The *gp\_configuration\_history* table contains information about system changes related to fault detection and recovery operations. The *fts\_probe* process logs data to this table, as do certain related management utilities such as *gpcheck*, *gprecoverseg*, and *gpinitssystem*. For example, when you add a new segment and mirror segment to the system, records for these events are logged to *gp\_configuration\_history*.

The event descriptions stored in this table may be helpful for troubleshooting serious system issues in collaboration with Greenplum support technicians.

This table is populated only on the master. This table is defined in the *pg\_global* tablespace, meaning it is globally shared across all databases in the system.

**Table 3.1** pg\_catalog.gp\_configuration\_history

column	type	references	description
time	timestamp with time zone		Timestamp for the event recorded.
dbid	smallint	<i>gp_segment_configuration.dbid</i>	System-assigned ID. The unique identifier of a segment (or master) instance.
desc	text		Text description of the event.

For information about *gpcheck*, *gprecoverseg*, and *gpinitssystem*, see the *Greenplum Database Utility Guide*.

## gp\_distributed\_log

The *gp\_distributed\_log* view contains status information about distributed transactions and their associated local transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the status of distributed transactions.

**Table 3.2** pg\_catalog.gp\_distributed\_log

column	type	references	description
segment_id	smallint	<i>gp_segment_configuration.content</i>	The content id if the segment. The master is always -1 (no content).
dbid	small_int	<i>gp_segment_configuration.dbid</i>	The unique id of the segment instance.
distributed_xid	xid		The global transaction id.
distributed_id	text		A system assigned ID for a distributed transaction.
status	text		The status of the distributed transaction (Committed or Aborted).
local_transaction	xid		The local transaction ID.

## gp\_distributed\_xacts

The *gp\_distributed\_xacts* view contains information about Greenplum Database distributed transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the currently active sessions and their associated distributed transactions.

**Table 3.3** pg\_catalog.gp\_distributed\_xacts

column	type	references	description
distributed_xid	xid		The transaction ID used by the distributed transaction across the Greenplum Database array.
distributed_id	text		The distributed transaction identifier. It has 2 parts — a unique timestamp and the distributed transaction number.
state	text		The current state of this session with regards to distributed transactions.
gp_session_id	int		The ID number of the Greenplum Database session associated with this transaction.
xmin_distributed_snapshot	xid		The minimum distributed transaction number found among all open transactions when this transaction was started. It is used for MVCC distributed snapshot purposes.

---

## gp\_distribution\_policy

The *gp\_distribution\_policy* table contains information about Greenplum Database tables and their policy for distributing table data across the segments. This table is populated only on the master. This table is not globally shared, meaning each database has its own copy of this table.

**Table 3.4** pg\_catalog.gp\_distribution\_policy

column	type	references	description
localoid	oid	<i>pg_class.oid</i>	The table object identifier (OID).
attrnums	smallint[]	<i>pg_attribute.attnum</i>	The column number(s) of the distribution column(s).

## gpexpand.expansion\_progress

The *gpexpand.expansion\_progress* view contains information about the status of a system expansion operation. The view provides calculations of the estimated rate of table redistribution and estimated time to completion.

Status for specific tables involved in the expansion is stored in *gpexpand.status\_detail*..

**Table 3.5** gpexpand.expansion\_progress

column	type	references	description
name	text		Name for the data field provided Includes:  Bytes Left Bytes Done Estimated Expansion Rate Estimated Time to Completion Tables Expanded Tables Left
value	text		The value for the progress data. For example:  Estimated Expansion Rate - 9.75667095996092 MB/s

## gpexpand.status

The *gpexpand.status* table contains information about the status of a system expansion operation. Status for specific tables involved in the expansion is stored in *gpexpand.status\_detail*.

In a normal expansion operation it is not necessary to modify the data stored in this table. .

**Table 3.6** gpexpand.status

column	type	references	description
status	text		Tracks the status of an expansion operation. Valid values are: SETUP SETUP DONE EXPANSION STARTED EXPANSION STOPPED COMPLETED
updated	timestamp with time zone		Timestamp of the last change in status.

## gpexpand.status\_detail

The *gpexpand.status\_detail* table contains information about the status of tables involved in a system expansion operation. You can query this table to determine the status of tables being expanded, or to view the start and end time for completed tables.

This table also stores related information about the table such as the oid, disk size, and normal distribution policy and key. Overall status information for the expansion is stored in *gpexpand.status*.

In a normal expansion operation it is not necessary to modify the data stored in this table. .

**Table 3.7** gpexpand.status\_detail

column	type	references	description
dbname	text		Name of the database to which the table belongs.
fq_name	text		Fully qualified name of the table.
schema_oid	oid		OID for the schema of the database to which the table belongs.
table_oid	oid		OID of the table.
distribution_policy	smallint()		Array of column IDs for the distribution key of the table.
distribution_policy_names	text		Column names for the hash distribution key.
distribution_policy_coloids	text		Column IDs for the distribution keys of the table.
storage_options	text		Not enabled in this release. Do not update this field.
rank	int		Rank determines the order in which tables are expanded. The expansion utility will sort on rank and expand the lowest-ranking tables first.
status	text		Status of expansion for this table. Valid values are: NOT STARTED IN PROGRESS FINISHED NO LONGER EXISTS
last updated	timestamp with time zone		Timestamp of the last change in status for this table.
expansion started	timestamp with time zone		Timestamp for the start of the expansion of this table. This field is only populated after a table is successfully expanded.

**Table 3.7** gpexpand.status\_detail

column	type	references	description
expansion finished	timestamp with time zone		Timestamp for the completion of expansion of this table.
source bytes			The size of disk space associated with the source table. Due to table bloat in heap tables and differing numbers of segments after expansion, it is not expected that the final number of bytes will equal the source number. This information is tracked to help provide progress measurement to aid in duration estimation for the end-to-end expansion operation.

## gp\_fastsequence

The *gp\_fastsequence* table contains information about indexes on append-optimized column-oriented tables. It is used to track the maximum row number used by a file segment of an append-optimized column-oriented table.

**Table 3.8** pg\_catalog.gp\_fastsequence

column	type	references	description
objid	oid	<i>pg_class.oid</i>	Object id of the <i>pg_aoseg.pg_aocsseg_*</i> table used to track append-optimized file segments.
objmod	bigint		Object modifier.
last_sequence	bigint		The last sequence number used by the object.

---

## gp\_fault\_strategy

The *gp\_fault\_strategy* table specifies the fault action.

**Table 3.9** pg\_catalog.gp\_fault\_strategy

column	type	references	description
fault_strategy	char		The mirror failover action to take when a segment failure occurs: n = nothing. f = file-based failover. s = SAN-based failover.

---

## gp\_global\_sequence

The *gp\_global\_sequence* table contains the log sequence number position in the transaction log, which is used by the file replication process to determine the file blocks to replicate from a primary to a mirror segment.

**Table 3.10** pg\_catalog.gp\_global\_sequence

column	type	references	description
sequence_num	bigint		log sequence number position in the transaction log

## gp\_id

The *gp\_id* system catalog table identifies the Greenplum Database system name and number of segments for the system. It also has *local* values for the particular database instance (segment or master) on which the table resides. This table is defined in the *pg\_global* tablespace, meaning it is globally shared across all databases in the system.

**Table 3.11** pg\_catalog.gp\_id

column	type	references	description
gpname	name		The name of this Greenplum Database system.
numsegments	integer		The number of segments in the Greenplum Database system.
dbid	integer		The unique identifier of this segment (or master) instance.
content	integer		The ID for the portion of data on this segment instance. A primary and its mirror will have the same content ID. For a segment the value is from 0- <i>N</i> , where <i>N</i> is the number of segments in Greenplum Database. For the master, the value is -1.

## gp\_interfaces

The *gp\_interfaces* table contains information about network interfaces on segment hosts. This information, joined with data from *gp\_db\_interfaces*, is used by the system to optimize the usage of available network interfaces for various purposes, including fault detection.

**Table 3.12** gp\_interfaces

column	type	references	description
interfaceid	smallint		System-assigned ID. The unique identifier of a network interface.
address	name		Hostname address for the segment host containing the network interface. Can be a numeric IP address or a hostname.
status	smallint		Status for the network interface. A value of 0 indicates that the interface is unavailable.

## gp\_persistent\_database\_node

The *gp\_persistent\_database\_node* table keeps track of the status of file system objects in relation to the transaction status of database objects. This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process.

**Table 3.13** pg\_catalog.gp\_persistent\_database\_node

column	type	references	description
tablespace_oid	oid	pg_tablespace.oid	Table space object id.
database_oid	oid	pg_database.oid	Database object id.
persistent_state	smallint		0 - free 1 - create pending 2 - created 3 - drop pending 4 - aborting create 5 - "Just in Time" create pending 6 - bulk load create pending
mirror_existence_state	smallint		0 - none 1 - not mirrored 2 - mirror create pending 3 - mirrorcreated 4 - mirror down before create 5 - mirror down during create 6 - mirror drop pending 7 - only mirror drop remains
parent_xid	integer		Global transaction id.
persistent_serial_num	bigint		Log sequence number position in the transaction log for a file block.
previous_free_tid	tid		Used by Greenplum Database to internally manage persistent representations of file system objects.

## gp\_persistent\_filespace\_node

The *gp\_persistent\_filespace\_node* table keeps track of the status of file system objects in relation to the transaction status of filespace objects. This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process.

**Table 3.14** pg\_catalog.gp\_persistent\_filespace\_node

column	type	references	description
filespace_oid	oid	pg_filespace.oid	object id of the filespace
db_id_1	smallint		primary segment id
location_1	text		primary filesystem location
db_id_2	smallint		mirror segment id
location_2	text		mirror filesystem location
persistent_state	smallint		0 - free 1 - create pending 2 - created 3 - drop pending 4 - aborting create 5 - "Just in Time" create pending 6 - bulk load create pending
mirror_existence_state	smallint		0 - none 1 - not mirrored 2 - mirror create pending 3 - mirrorcreated 4 - mirror down before create 5 - mirror down during create 6 - mirror drop pending 7 - only mirror drop remains
parent_xid	integer		Global transaction id.
persistent_serial_num	bigint		Log sequence number position in the transaction log for a file block.
previous_free_tid	tid		Used by Greenplum Database to internally manage persistent representations of file system objects.

## gp\_persistent\_relation\_node

The *gp\_persistent\_relation\_node* table keeps track of the status of file system objects in relation to the transaction status of relation objects (tables, view, indexes, and so on). This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process.

**Table 3.15** pg\_catalog.gp\_persistent\_relation\_node

column	type	references	description
tablespace_oid	oid	<i>pg_tablespace.oid</i>	Tablespace object id
database_oid	oid	<i>pg_database.oid</i>	Database object id
relfilenode_oid	oid	<i>pg_class.relfilenode</i>	The object id of the relation file node.
segment_file_num	integer		For append-optimized tables, the append-optimized segment file number.
relation_storage_manager	smallint		Whether the relation is heap storage or append-optimized storage.
persistent_state	smallint		0 - free 1 - create pending 2 - created 3 - drop pending 4 - aborting create 5 - "Just in Time" create pending 6 - bulk load create pending
mirror_existence_state	smallint		0 - none 1 - not mirrored 2 - mirror create pending 3 - mirrorcreated 4 - mirror down before create 5 - mirror down during create 6 - mirror drop pending 7 - only mirror drop remains
parent_xid	integer		Global transaction id.
persistent_serial_num	bigint		Log sequence number position in the transaction log for a file block.
previous_free_tid	tid		Used by Greenplum Database to internally manage persistent representations of file system objects.

## gp\_persistent\_tablespace\_node

The *gp\_persistent\_tablespace\_node* table keeps track of the status of file system objects in relation to the transaction status of tablespace objects. This information is used to make sure the state of the system catalogs and the file system files persisted to disk are synchronized. This information is used by the primary to mirror file replication process

**Table 3.16** pg\_catalog.gp\_persistent\_tablespace\_node

column	type	references	description
filespace_oid	oid	pg_filespace.oid	Filespace object id
tablespace_oid	oid	pg_tablespace.oid	Tablespace object id
persistent_state	smallint		0 - free 1 - create pending 2 - created 3 - drop pending 4 - aborting create 5 - "Just in Time" create pending 6 - bulk load create pending
mirror_existence_state	smallint		0 - none 1 - not mirrored 2 - mirror create pending 3 - mirrorcreated 4 - mirror down before create 5 - mirror down during create 6 - mirror drop pending 7 - only mirror drop remains
parent_xid	integer		Global transaction id.
persistent_serial_num	bigint		Log sequence number position in the transaction log for a file block.
previous_free_tid	tid		Used by Greenplum Database to internally manage persistent representations of file system objects.

## gp\_pgdatabase

The *gp\_pgdatabase* view shows status information about the Greenplum segment instances and whether they are acting as the mirror or the primary. This view is used internally by the Greenplum fault detection and recovery utilities to determine failed segments.

**Table 3.17** pg\_catalog.gp\_pgdatabase

column	type	references	description
dbid	smallint	<i>gp_segment_configuration.dbid</i>	System-assigned ID. The unique identifier of a segment (or master) instance.
isprimary	boolean	<i>gp_segment_configuration.role</i>	Whether or not this instance is active. Is it currently acting as the primary segment (as opposed to the mirror).
content	smallint	<i>gp_segment_configuration.content</i>	The ID for the portion of data on an instance. A primary segment instance and its mirror will have the same content ID. For a segment the value is from 0- <i>N</i> , where <i>N</i> is the number of segments in Greenplum Database. For the master, the value is -1.
definedprimary	boolean	<i>gp_segment_configuration.preferred_role</i>	Whether or not this instance was defined as the primary (as opposed to the mirror) at the time the system was initialized.

## gp\_relation\_node

The *gp\_relation\_node* table contains information about the file system objects for a relation (table, view, index, and so on).

**Table 3.18** pg\_catalog.gp\_relation\_node

column	type	references	description
relfilenode_oid	oid	<i>pg_class.relfilenode</i>	The object id of the relation file node.
segment_file_num	integer		For append-optimized tables, the append-optimized segment file number.
persistent_tid	tid		Used by Greenplum Database to internally manage persistent representations of file system objects.
persistent_serial_num	bigint		Log sequence number position in the transaction log for a file block.

## gp\_resqueue\_status

The *gp\_toolkit.gp\_resqueue\_status* view allows administrators to see status and activity for a workload management resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

**Table 3.1** gp\_toolkit.gp\_resqueue\_status

column	type	references	description
queueid	oid	<i>gp_toolkit.gp_resqueue_queueid</i>	The ID of the resource queue.
rsqname	name	<i>gp_toolkit.gp_resqueue_rsqname</i>	The name of the resource queue.
rsqcountlimit	real	<i>gp_toolkit.gp_resqueue_rsqcountlimit</i>	The active query threshold of the resource queue. A value of -1 means no limit.
rsqcountvalue	real	<i>gp_toolkit.gp_resqueue_rsqcountvalue</i>	The number of active query slots currently being used in the resource queue.
rsqcostlimit	real	<i>gp_toolkit.gp_resqueue_rsqcostlimit</i>	The query cost threshold of the resource queue. A value of -1 means no limit.
rsqcostvalue	real	<i>gp_toolkit.gp_resqueue_rsqcostvalue</i>	The total cost of all statements currently in the resource queue.
rsqmemorylimit	real	<i>gp_toolkit.gp_resqueue_rsqmemorylimit</i>	The memory limit for the resource queue.
rsqmemoryvalue	real	<i>gp_toolkit.gp_resqueue_rsqmemoryvalue</i>	The total memory used by all statements currently in the resource queue.
rsqwaiters	integer	<i>gp_toolkit.gp_resqueue_rsqwaiter</i>	The number of statements currently waiting in the resource queue.
rsqholders	integer	<i>gp_toolkit.gp_resqueue_rsqholders</i>	The number of statements currently running on the system from this resource queue.

## gp\_san\_configuration

The *gp\_san\_configuration* table contains mount-point information for SAN failover.

**Table 3.2** pg\_catalog.gp\_san\_configuration

column	type	references	description
mountid	smallint		A value that identifies the mountpoint for the primary and mirror hosts. This is the primary key which is referred to by the value that appears in the <i>san_mounts</i> structure in <i>gp_segment_configuration</i> .
active_host	char		The current active host. <i>p</i> indicates primary, and <i>m</i> indicates mirror.
san_type	char		The type of shared storage in use. <i>n</i> indicates NFS, and <i>e</i> indicates EMC SAN.
primary_host	text		The name of the primary host system
primary_mountpoint	text		The mount point for the primary host.
primary_device	text		A string specifying the device to mount on the primary mountpoint. For NFS, this string is similar to: <i>nfs-server:/exported/fs</i> . For EMC this is a larger string that includes the WWN for the storage processor, the storage-processor IP, and the storage-group name.  The <i>primary_device</i> field is identical to the <i>mirror_device</i> field.
mirror_host	text		The name or the mirror/backup host system.

**Table 3.2** pg\_catalog.gp\_san\_configuration

column	type	references	description
mirror_mountpoint	text		The mount point for the mirror/backup host.
mirror_device	text		<p>A string specifying the device to mount on the mirror mountpoint. For NFS, this string is similar to: <code>nfs-server:/exported/fs</code>. For EMC this is a larger string that includes the WWN for the storage processor, the storage-processor IP, and the storage-group name.</p> <p>The <code>mirror_device</code> field is identical to the <code>primary_device</code> field.</p>

## gp\_segment\_configuration

The *gp\_segment\_configuration* table contains information about mirroring and segment configuration.

**Table 3.3** pg\_catalog.gp\_segment\_configuration

column	type	references	description
dbid	smallint		The unique identifier of a segment (or master) instance.
content	smallint		The content identifier for a segment instance. A primary segment instance and its corresponding mirror will always have the same content identifier. For a segment the value is from 0- <i>N</i> , where <i>N</i> is the number of primary segments in the system. For the master, the value is always -1.
role	char		The role that a segment is currently running as. Values are <i>p</i> (primary) or <i>m</i> (mirror).
preferred_role	char		The role that a segment was originally assigned at initialization time. Values are <i>p</i> (primary) or <i>m</i> (mirror).
mode	char		The synchronization status of a segment with its mirror copy. Values are <i>s</i> (synchronized), <i>c</i> (change logging), or <i>r</i> (resyncing).
status	char		The fault status of a segment. Values are <i>u</i> (up) or <i>d</i> (down).
port	integer		The TCP port the database server listener process is using.
hostname	text		The hostname of a segment host.
address	text		The hostname used to access a particular segment on a segment host. This value may be the same as <i>hostname</i> in systems upgraded from 3.x or on systems that do not have per-interface hostnames configured.
replication_port	integer		The TCP port the file block replication process is using to keep primary and mirror segments synchronized.
san_mounts	int2vector	<a href="#">gp_san_configuration.oid</a>	An array of references to the <a href="#">gp_san_configuration</a> table. Only used on systems that were initialized using sharred storage.

## gp\_transaction\_log

The *gp\_transaction\_log* view contains status information about transactions local to a particular segment. This view allows you to see the status of local transactions.

**Table 3.4** pg\_catalog.gp\_transaction\_log

column	type	references	description
segment_id	smallint	<i>gp_segment_configuration.content</i>	The content id if the segment. The master is always -1 (no content).
dbid	smallint	<i>gp_segment_configuration.dbid</i>	The unique id of the segment instance.
transaction	xid		The local transaction ID.
status	text		The status of the local transaction (Committed or Aborted).

---

## gp\_version\_at\_initdb

The *gp\_version\_at\_initdb* table is populated on the master and each segment in the Greenplum Database system. It identifies the version of Greenplum Database used when the system was first initialized. This table is defined in the *pg\_global* tablespace, meaning it is globally shared across all databases in the system.

**Table 3.5** pg\_catalog.gp\_version

column	type	references	description
schemaversion	integer		Schema version number.
productversion	text		Product version number.

## pg\_aggregate

The *pg\_aggregate* table stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are *sum*, *count*, and *max*. Each entry in *pg\_aggregate* is an extension of an entry in *pg\_proc*. The *pg\_proc* entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

**Table 3.6** pg\_catalog.pg\_aggregate

column	type	references	description
aggfnoid	regproc	<i>pg_proc.oid</i>	Aggregate function OID
aggtransfn	regproc	<i>pg_proc.oid</i>	Transition function OID
aggprelimfn	regproc		Preliminary function OID (zero if none)
aggfinalfn	regproc	<i>pg_proc.oid</i>	Final function OID (zero if none)
agginitval	text		The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is NULL, the transition state value starts out NULL
agginvtransfn	regproc	<i>pg_proc.oid</i>	The OID in <i>pg_proc</i> of the inverse function of <i>aggtransfn</i>
agginvprelimfn	regproc	<i>pg_proc.oid</i>	The OID in <i>pg_proc</i> of the inverse function of <i>aggprelimfn</i>
aggordered	Boolean		If <i>true</i> , the aggregate is defined as <i>ORDERED</i> .
aggsortop	oid	<i>pg_operator.oid</i>	Associated sort operator OID (zero if none)
aggtranstype	oid	<i>pg_type.oid</i>	Data type of the aggregate function's internal transition (state) data

## pg\_am

The *pg\_am* table stores information about index access methods. There is one row for each index access method supported by the system.

**Table 3.7** pg\_catalog.pg\_am

column	type	references	description
amname	name		Name of the access method
amstrategies	int2		Number of operator strategies for this access method
amsupport	int2		Number of support routines for this access method
amorderstrategy	int2		Zero if the index offers no sort order, otherwise the strategy number of the strategy operator that describes the sort order
amcanunique	boolean		Does the access method support unique indexes?
amcanmulticol	boolean		Does the access method support multicolumn indexes?
amoptionalkey	boolean		Does the access method support a scan without any constraint for the first index column?
amindexnulls	boolean		Does the access method support null index entries?
amstorage	boolean		Can index storage data type differ from column data type?
amclusterable	boolean		Can an index of this type be clustered on?
aminsert	regproc	<i>pg_proc.oid</i>	"Insert this tuple" function
ambeginscan	regproc	<i>pg_proc.oid</i>	"Start new scan" function
amgettup	regproc	<i>pg_proc.oid</i>	"Next valid tuple" function
amgetmulti	regproc	<i>pg_proc.oid</i>	"Fetch multiple tuples" function
amrescan	regproc	<i>pg_proc.oid</i>	"Restart this scan" function
amendscan	regproc	<i>pg_proc.oid</i>	"End this scan" function
ammarkpos	regproc	<i>pg_proc.oid</i>	"Mark current scan position" function
amrestrpos	regproc	<i>pg_proc.oid</i>	"Restore marked scan position" function
ambuild	regproc	<i>pg_proc.oid</i>	"Build new index" function
ambulkdelete	regproc	<i>pg_proc.oid</i>	Bulk-delete function
amvacuumcleanup	regproc	<i>pg_proc.oid</i>	Post-VACUUM cleanup function

**Table 3.7** pg\_catalog.pg\_am

column	type	references	description
amcostestimate	regproc	<i>pg_proc.oid</i>	Function to estimate cost of an index scan
amoptions	regproc	<i>pg_proc.oid</i>	Function to parse and validate reloptions for an index

## pg\_amop

The *pg\_amop* table stores information about operators associated with index access method operator classes. There is one row for each operator that is a member of an operator class.

**Table 3.8** pg\_catalog.pg\_amop

column	type	references	description
amopclaid	oid	<i>pg_opclass.oid</i>	The index operator class this entry is for
amopsubtype	oid	<i>pg_type.oid</i>	Subtype to distinguish multiple entries for one strategy; zero for default
amopstrategy	int2		Operator strategy number
amopreqcheck	boolean		Index hit must be rechecked
amopopr	oid	<i>pg_operator.oid</i>	OID of the operator

## pg\_amproc

The *pg\_amproc* table stores information about support procedures associated with index access method operator classes. There is one row for each support procedure belonging to an operator class.

**Table 3.9** pg\_catalog.pg\_amproc

column	type	references	description
amopclaid	oid	<i>pg_opclass.oid</i>	The index operator class this entry is for
amproctype	oid	<i>pg_type.oid</i>	Subtype, if cross-type routine, else zero
amprocnum	int2		Support procedure number
amproc	regproc	<i>pg_proc.oid</i>	OID of the procedure

## pg\_appendonly

The *pg\_appendonly* table contains information about the storage options and other characteristics of append-optimized tables.

**Table 3.10** pg\_catalog.pg\_appendonly

column	type	references	description
relid	oid		The table object identifier (OID) of the compressed table.
blocksize	integer		Block size used for compression of append-optimized tables. Valid values are 8K - 2M. Default is 32K.
safefswritesize	integer		Minimum size for safe write operations to append-optimized tables in a non-mature file system. Commonly set to a multiple of the extent size of the file system; for example, Linux ext3 is 4096 bytes, so a value of 32768 is commonly used.
majorversion	smallint		The major version number of the <i>pg_appendonly</i> table.
minorversion	smallint		The minor version number of the <i>pg_appendonly</i> table.
checksum	boolean		A checksum value that is stored to compare the state of a block of data at compression time and at scan time to ensure data integrity. This data is stored only if <i>gp_appendonly_verify_block_checksums</i> is enabled (this parameter is disabled by default to optimize performance).
compresstype	text		Type of compression used to compress append-optimized tables. Valid values are <i>zlib</i> (gzip compression) and <i>quicklz</i> .
compresslevel	smallint		The compression level, with compression ratio increasing from 1 to 9. When <i>quicklz</i> is specified for <i>compresstype</i> , valid values are 1 or 3. With <i>zlib</i> specified, valid values are 1-9.
columnstore	boolean		1 for column-oriented storage, 0 for row-oriented storage.
segrelid	oid		Table on-disk segment file id.
segidxid	oid		Index on-disk segment file id.
blkdirrelid	oid		Block used for on-disk column-oriented table file.

**Table 3.10** pg\_catalog.pg\_appendonly

column	type	references	description
blkdiridxid	oid		Block used for on-disk column-oriented index file.
visimaprelid	oid		Visibility map for the table.
visimapidxid	oid		B-tree index on the visibility map.

## pg\_attrdef

The *pg\_attrdef* table stores column default values. The main information about columns is stored in *pg\_attribute*. Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

**Table 3.11** pg\_catalog.pg\_attrdef

column	type	references	description
adrelid	oid	<i>pg_class.oid</i>	The table this column belongs to
adnum	int2	<i>pg_attribute.attnum</i>	The number of the column
adbin	text		The internal representation of the column default value
adsrc	text		A human-readable representation of the default value. This field is historical, and is best not used.

## pg\_attribute

The *pg\_attribute* table stores information about table columns. There will be exactly one *pg\_attribute* row for every column in every table in the database. (There will also be attribute entries for indexes, and all objects that have *pg\_class* entries.) The term attribute is equivalent to column.

**Table 3.12** pg\_catalog.pg\_attribute

column	type	references	description
attrelid	oid	<i>pg_class.oid</i>	The table this column belongs to
attname	name		The column name
atttypid	oid	<i>pg_type.oid</i>	The data type of this column
attstattarget	int4		Controls the level of detail of statistics accumulated for this column by <i>ANALYZE</i> . A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, it is both the target number of “most common values” to collect, and the target number of histogram bins to create.
attlen	int2		A copy of <i>pg_type.typelen</i> of this column’s type.
attnum	int2		The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <i>oid</i> , have (arbitrary) negative numbers.
attndims	int4		Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means it is an array)
attcacheoff	int4		Always -1 in storage, but when loaded into a row descriptor in memory this may be updated to cache the offset of the attribute within the row
atttypmod	int4		Records type-specific data supplied at table creation time (for example, the maximum length of a <i>varchar</i> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need it.
attbyval	boolean		A copy of <i>pg_type.typbyval</i> of this column’s type

**Table 3.12** pg\_catalog.pg\_attribute

column	type	references	description
attstorage	char		Normally a copy of <i>pg_type.typstorage</i> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.
attalign	char		A copy of <i>pg_type.typalign</i> of this column's type
attnotnull	boolean		This represents a not-null constraint. It is possible to change this column to enable or disable the constraint.
atthasdef	boolean		This column has a default value, in which case there will be a corresponding entry in the <i>pg_attrdef</i> catalog that actually defines the value
attisdropped	boolean		This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL
attislocal	boolean		This column is defined locally in the relation. Note that a column may be locally defined and inherited simultaneously
attinhcount	int4		The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed

---

## pg\_attribute\_encoding

The *pg\_attribute\_encoding* system catalog table contains column storage information.

**Table 3.13** pg\_catalog.pg\_attribute\_encoding

column	type	modifiers	storage	description
attreid	oid	not null	plain	Foreign key to pg_attribute.attreid
attnum	smallint	not null	plain	Foreign key to pg_attribute.attnum
attoptions	text [ ]		extended	The options

## pg\_auth\_members

The *pg\_auth\_members* system catalog table shows the membership relations between roles. Any non-circular set of relationships is allowed. Because roles are system-wide, *pg\_auth\_members* is shared across all databases of a Greenplum Database system.

**Table 3.14** pg\_catalog.pg\_auth\_members

column	type	references	description
roleid	oid	<i>pg_authid.oid</i>	ID of the parent-level (group) role
member	oid	<i>pg_authid.oid</i>	ID of a member role
grantor	oid	<i>pg_authid.oid</i>	ID of the role that granted this membership
admin_option	boolean		True if role member may grant membership to others

## pg\_authid

The *pg\_authid* table contains information about database authorization identifiers (roles). A role subsumes the concepts of users and groups. A user is a role with the *rolcanlogin* flag set. Any role (with or without *rolcanlogin*) may have other roles as members. See *pg\_auth\_members*.

Since this catalog contains passwords, it must not be publicly readable. *pg\_roles* is a publicly readable view on *pg\_authid* that blanks out the password field.

Because user identities are system-wide, *pg\_authid* is shared across all databases in a Greenplum Database system: there is only one copy of *pg\_authid* per system, not one per database.

**Table 3.15** pg\_catalog.pg\_authid

column	type	references	description
rolname	name		Role name
rolsuper	boolean		Role has superuser privileges
rolinherit	boolean		Role automatically inherits privileges of roles it is a member of
rolcreaterole	boolean		Role may create more roles
rolcreatedb	boolean		Role may create databases
rolcatupdate	boolean		Role may update system catalogs directly. (Even a superuser may not do this unless this column is true)
rolcanlogin	boolean		Role may log in. That is, this role can be given as the initial session authorization identifier
rolconnlimit	int4		For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit
rolpassword	text		Password (possibly encrypted); NULL if none
rolvaliduntil	timestampz		Password expiry time (only used for password authentication); NULL if no expiration
rolconfig	text[]		Session defaults for server configuration parameters

## pg\_cast

The catalog *pg\_cast* stores data type conversion paths, both built-in paths and those defined with `CREATE CAST`. The cast functions listed in *pg\_cast* must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a *pg\_cast* entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent ‘length coercion functions’ that coerce values of the type to be legal for a particular type modifier value. Note however that at present there is no support for associating non-default type modifiers with user-created data types, and so this facility is only of use for the small number of built-in types that have type modifier syntax built into the grammar.

When a *pg\_cast* entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

**Table 3.16** *pg\_catalog.pg\_cast*

column	type	references	description
castsource	oid	<i>pg_type.oid</i>	OID of the source data type.
casttarget	oid	<i>pg_type.oid</i>	OID of the target data type.
castfunc	oid	<i>pg_proc.oid</i>	The OID of the function to use to perform this cast. Zero is stored if the data types are binary compatible (that is, no run-time operation is needed to perform the cast).
castcontext	char		Indicates what contexts the cast may be invoked in. <code>e</code> means only as an explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases.

## pg\_class

The system catalog table *pg\_class* catalogs tables and most everything else that has columns or is otherwise similar to a table (also known as *relations*). This includes indexes (see also *pg\_index*), sequences, views, composite types, and TOAST tables. Not all columns are meaningful for all relation types.

**Table 3.17** pg\_catalog.pg\_class

column	type	references	description
relname	name		Name of the table, index, view, etc.
relnamespace	oid	<i>pg_namespace.oid</i>	The OID of the namespace (schema) that contains this relation
reltype	oid	<i>pg_type.oid</i>	The OID of the data type that corresponds to this table's row type, if any (zero for indexes, which have no <i>pg_type</i> entry)
relowner	oid	<i>pg_authid.oid</i>	Owner of the relation
relam	oid	<i>pg_am.oid</i>	If this is an index, the access method used (B-tree, Bitmap, hash, etc.)
relfilenode	oid		Name of the on-disk file of this relation; 0 if none.
reltablespace	oid	<i>pg_tablespace.oid</i>	The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. (Not meaningful if the relation has no on-disk file.)
relpages	int4		Size of the on-disk representation of this table in pages (of 32K each). This is only an estimate used by the planner. It is updated by <i>VACUUM</i> , <i>ANALYZE</i> , and a few DDL commands.
reltuples	float4		Number of rows in the table. This is only an estimate used by the planner. It is updated by <i>VACUUM</i> , <i>ANALYZE</i> , and a few DDL commands.
reltoastrelid	oid	<i>pg_class.oid</i>	OID of the TOAST table associated with this table, 0 if none. The TOAST table stores large attributes "out of line" in a secondary table.
reltoastidxid	oid	<i>pg_class.oid</i>	For a TOAST table, the OID of its index. 0 if not a TOAST table.
relaosegidxid	oid		Deprecated in Greenplum Database 3.4.
relaosegreid	oid		Deprecated in Greenplum Database 3.4.

**Table 3.17** pg\_catalog.pg\_class

column	type	references	description
relhasindex	boolean		True if this is a table and it has (or recently had) any indexes. This is set by <code>CREATE INDEX</code> , but not cleared immediately by <code>DROP INDEX</code> . <code>VACUUM</code> will clear if it finds the table has no indexes.
relisshared	boolean		True if this table is shared across all databases in the system. Only certain system catalog tables are shared.
relkind	char		The type of object <i>r</i> = heap or append-optimized table, <i>i</i> = index, <i>s</i> = sequence, <i>v</i> = view, <i>c</i> = composite type, <i>t</i> = TOAST value, <i>o</i> = internal append-optimized segment files and EOFs, <i>c</i> = composite type, <i>u</i> = uncataloged temporary heap table
relstorage	char		The storage mode of a table <i>a</i> = append-optimized, <i>h</i> = heap, <i>v</i> = virtual, <i>x</i> = external table.
relnatts	int2		Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <i>pg_attribute</i> .
relchecks	int2		Number of check constraints on the table.
reltriggers	int2		Number of triggers on the table.
relukeys	int2		Unused
relfkeys	int2		Unused
relrefs	int2		Unused
relhasoids	boolean		True if an OID is generated for each row of the relation.
relhaskey	boolean		True if the table has (or once had) a primary key.
relhasrules	boolean		True if table has rules.
relhassubclass	boolean		True if table has (or once had) any inheritance children.

**Table 3.17** pg\_catalog.pg\_class

column	type	references	description
relfrozenxid	xid		All transaction IDs before this one have been replaced with a permanent (frozen) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow <i>pg_clog</i> to be shrunk. Zero (InvalidTransactionId) if the relation is not a table.
relacl	aclitem[]		Access privileges assigned by GRANT and REVOKE.
reloptions	text[]		Access-method-specific options, as “keyword=value” strings.

## pg\_compression

The *pg\_compression* system catalog table describes the compression methods available..

**Table 3.18** pg\_catalog.pg\_compression

column	type	modifiers	storage	description
compname	name	not null	plain	Name of the compression
compconstructor	regproc	not null	plain	Name of compression constructor
compdestructor	regproc	not null	plain	Name of compression destructor
compcompressor	regproc	not null	plain	Name of the compressor
compdecompressor	regproc	not null	plain	Name of the decompressor
compvalidator	regproc	not null	plain	Name of the compression validator
compowner	oid	not null	plain	oid from pg_authid

## pg\_constraint

The *pg\_constraint* system catalog table stores check, primary key, unique, and foreign key constraints on tables. Column constraints are not treated specially. Every column constraint is equivalent to some table constraint. Not-null constraints are represented in the *pg\_attribute* catalog. Check constraints on domains are stored here, too.

**Table 3.19** pg\_catalog.pg\_constraint

column	type	references	description
conname	name		Constraint name (not necessarily unique!)
connamespace	oid	<i>pg_namespace.oid</i>	The OID of the namespace (schema) that contains this constraint.
contype	char		c = check constraint, f = foreign key constraint, p = primary key constraint, u = unique constraint.
condeferrable	boolean		Is the constraint deferrable?
condeferred	boolean		Is the constraint deferred by default?
conrelid	oid	<i>pg_class.oid</i>	The table this constraint is on; 0 if not a table constraint.
contypid	oid	<i>pg_type.oid</i>	The domain this constraint is on; 0 if not a domain constraint.
confrelid	oid	<i>pg_class.oid</i>	If a foreign key, the referenced table; else 0.
confupdtype	char		Foreign key update action code.
confdeltype	char		Foreign key deletion action code.
confmatchtype	char		Foreign key match type.
conkey	int2[]	<i>pg_attribute.attnum</i>	If a table constraint, list of columns which the constraint constrains.
confkey	int2[]	<i>pg_attribute.attnum</i>	If a foreign key, list of the referenced columns.
conbin	text		If a check constraint, an internal representation of the expression.
consrc	text		If a check constraint, a human-readable representation of the expression. This is not updated when referenced objects change; for example, it won't track renaming of columns. Rather than relying on this field, it is best to use <code>pg_get_constraintdef()</code> to extract the definition of a check constraint.

## pg\_conversion

The *pg\_conversion* system catalog table describes the available encoding conversion procedures as defined by `CREATE CONVERSION`.

**Table 3.20** pg\_catalog.pg\_conversion

column	type	references	description
conname	name		Conversion name (unique within a namespace).
connamespace	oid	<i>pg_namespace.oid</i>	The OID of the namespace (schema) that contains this conversion.
conowner	oid	<i>pg_authid.oid</i>	Owner of the conversion.
conforencoding	int4		Source encoding ID.
contoencoding	int4		Destination encoding ID.
conproc	regproc	<i>pg_proc.oid</i>	Conversion procedure.
condefault	boolean		True if this is the default conversion.

## pg\_database

The *pg\_database* system catalog table stores information about the available databases. Databases are created with the `CREATE DATABASE` SQL command. Unlike most system catalogs, *pg\_database* is shared across all databases in the system. There is only one copy of *pg\_database* per system, not one per database.

**Table 3.21** pg\_catalog.pg\_database

column	type	references	description
datname	name		Database name.
datdba	oid	<i>pg_authid.oid</i>	Owner of the database, usually the user who created it.
encoding	int4		Character encoding for this database. <i>pg_encoding_to_char()</i> can translate this number to the encoding name.
datistemplate	boolean		If true then this database can be used in the <code>TEMPLATE</code> clause of <code>CREATE DATABASE</code> to create a new database as a clone of this one.
dataallowconn	boolean		If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered.
datconnlimit	int4		Sets the maximum number of concurrent connections that can be made to this database. -1 means no limit.
datlastsysoid	oid		Last system OID in the database; useful particularly to <i>pg_dump/pg_dump</i> .
datfrozenxid	xid		All transaction IDs before this one have been replaced with a permanent (frozen) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <i>pg_clog</i> to be shrunk. It is the minimum of the per-table <i>pg_class.relfrozensid</i> values.
dattablespace	oid	<i>pg_tablespace.oid</i>	The default tablespace for the database. Within this database, all tables for which <i>pg_class.reltablespace</i> is zero will be stored in this tablespace. All non-shared system catalogs will also be there.

**Table 3.21** pg\_catalog.pg\_database

column	type	references	description
datconfig	text[]		Session defaults for user-settable server configuration parameters.
datacl	aclitem[]		Database access privileges as given by GRANT and REVOKE.

## pg\_depend

The *pg\_depend* system catalog table records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case. See also *pg\_shdepend*, which performs a similar function for dependencies involving objects that are shared across a Greenplum system.

In all cases, a *pg\_depend* entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by *deptype*:

- **DEPENDENCY\_NORMAL (n)** — A normal relationship between separately-created objects. The dependent object may be dropped without affecting the referenced object. The referenced object may only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.
- **DEPENDENCY\_AUTO (a)** — The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.
- **DEPENDENCY\_INTERNAL (i)** — The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not. Example: a trigger that's created to enforce a foreign-key constraint is made internally dependent on the constraint's *pg\_constraint* entry.
- **DEPENDENCY\_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

**Table 3.22** pg\_catalog.pg\_depend

column	type	references	description
classid	oid	<i>pg_class.oid</i>	The OID of the system catalog the dependent object is in.
objid	oid	any OID column	The OID of the specific dependent object.
objsubid	int4		For a table column, this is the column number. For all other object types, this column is zero.
refclassid	oid	<i>pg_class.oid</i>	The OID of the system catalog the referenced object is in.
refobjid	oid	any OID column	The OID of the specific referenced object.
refobjsubid	int4		For a table column, this is the referenced column number. For all other object types, this column is zero.
deptype	char		A code defining the specific semantics of this dependency relationship.

## pg\_description

The *pg\_description* system catalog table stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. Descriptions of many built-in system objects are provided in the initial contents of *pg\_description*. See also *pg\_shdescription*, which performs a similar function for descriptions involving objects that are shared across a Greenplum system.

**Table 3.23** pg\_catalog.pg\_description

column	type	references	description
objoid	oid	any OID column	The OID of the object this description pertains to.
classoid	oid	<i>pg_class.oid</i>	The OID of the system catalog this object appears in
objsubid	int4		For a comment on a table column, this is the column number. For all other object types, this column is zero.
description	text		Arbitrary text that serves as the description of this object.

## pg\_exttable

The *pg\_exttable* system catalog table is used to track external tables and web tables created by the `CREATE EXTERNAL TABLE` command.

**Table 3.24** pg\_catalog.pg\_exttable

column	type	references	description
reloid	oid	<i>pg_class.oid</i>	The OID of this external table.
location	text[]		The URI location(s) of the external table files.
fmttype	char		Format of the external table files: <code>t</code> for text, or <code>c</code> for csv.
fmtopts	text		Formatting options of the external table files, such as the field delimiter, null string, escape character, etc.
command	text		The OS command to execute when the external table is accessed.
rejectlimit	integer		The per segment reject limit for rows with errors, after which the load will fail.
rejectlimittype	char		Type of reject limit threshold: <code>r</code> for number of rows.
fmterrtbl	oid	<i>pg_class.oid</i>	The object id of the error table where format errors will be logged.
encoding	text		The client encoding.
writable	boolean		0 for readable external tables, 1 for writable external tables.

## pg\_filespace

The *pg\_filespace* table contains information about the tablespaces created in a Greenplum Database system. Every system contains a default filespace, *pg\_system*, which is a collection of all the data directory locations created at system initialization time.

A tablespace requires a file system location to store its database files. In Greenplum Database, the master and each segment (primary and mirror) needs its own distinct storage location. This collection of file system locations for all components in a Greenplum system is referred to as a filespace.

**Table 3.25** pg\_catalog.pg\_filespace

column	type	references	description
fsname	name		The name of the filespace.
fsowner	oid	pg_roles.oid	The object id of the role that created the filespace.

## pg\_filespace\_entry

A tablespace requires a file system location to store its database files. In Greenplum Database, the master and each segment (primary and mirror) needs its own distinct storage location. This collection of file system locations for all components in a Greenplum system is referred to as a *filesystem*. The *pg\_filespace\_entry* table contains information about the collection of file system locations across a Greenplum Database system that comprise a Greenplum Database filesystem.

**Table 3.26** pg\_catalog.pg\_filespace\_entry

column	type	references	description
fsefoid	OID	pg_filespace.oid	Object id of the filesystem.
fsedbld	integer	gp_segment_configuration.dbld	Segment id.
fselocation	text		File system location for this segment id.

## pg\_index

The *pg\_index* system catalog table contains part of the information about indexes. The rest is mostly in *pg\_class*.

**Table 3.27** pg\_catalog.pg\_index

column	type	references	description
indexrelid	oid	<i>pg_class.oid</i>	The OID of the <i>pg_class</i> entry for this index.
indrelid	oid	<i>pg_class.oid</i>	The OID of the <i>pg_class</i> entry for the table this index is for.
indnatts	int2		The number of columns in the index (duplicates <i>pg_class.relnatts</i> ).
indisunique	boolean		If true, this is a unique index.
indisprimary	boolean		If true, this index represents the primary key of the table. ( <i>indisunique</i> should always be true when this is true.)
indisclustered	boolean		If true, the table was last clustered on this index via the <code>CLUSTER</code> command.
indisvalid	boolean		If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries.
indkey	int2vector	<i>pg_attribute.attnum</i>	This is an array of <i>indnatts</i> values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.
indclass	oidvector	<i>pg_opclass.oid</i>	For each column in the index key this contains the OID of the operator class to use.

**Table 3.27** pg\_catalog.pg\_index

column	type	references	description
indexprs	text		Expression trees (in <code>nodeToString()</code> representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <i>indkey</i> . NULL if all index attributes are simple references.
indpred	text		Expression tree (in <code>nodeToString()</code> representation) for partial index predicate. NULL if not a partial index.

## pg\_inherits

The *pg\_inherits* system catalog table records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.) In Greenplum Database, inheritance relationships are created by both the `INHERITS` clause (standalone inheritance) and the `PARTITION BY` clause (partitioned child table inheritance) of `CREATE TABLE`.

**Table 3.28** pg\_catalog.pg\_inherits

column	type	references	description
inhrelid	oid	<i>pg_class.oid</i>	The OID of the child table.
inhparent	oid	<i>pg_class.oid</i>	The OID of the parent table.
inhseqno	int4		If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1.

## pg\_language

The *pg\_language* system catalog table registers languages in which you can write functions or stored procedures. It is populated by `CREATE LANGUAGE`.

**Table 3.29** pg\_catalog.pg\_language

column	type	references	description
lanname	name		Name of the language.
lanispl	boolean		This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this may be replaced by a different mechanism in the future.
lanpltrusted	boolean		True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers may create functions in untrusted languages.
lanplcallfoid	oid	<i>pg_proc.oid</i>	For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language.
lanvalidator	oid	<i>pg_proc.oid</i>	This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.
lanacl	aclitem[]		Access privileges for the language.

## pg\_largeobject

The *pg\_largeobject* system catalog table holds the data making up ‘large objects’. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or ‘pages’ small enough to be conveniently stored as rows in *pg\_largeobject*. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 8K).

Each row of *pg\_largeobject* holds data for one page of a large object, beginning at byte offset (*pageno* \* `LOBLKSIZE`) within the object. The implementation allows sparse storage: pages may be missing, and may be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

**Table 3.30** pg\_catalog.pg\_largeobject

column	type	references	description
loid	oid		Identifier of the large object that includes this page.
pageno	int4		Page number of this page within its large object (counting from zero).
data	bytea		Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and may be less.

## pg\_listener

The *pg\_listener* system catalog table supports the `LISTEN` and `NOTIFY` commands. A listener creates an entry in *pg\_listener* for each notification name it is listening for. A notifier scans and updates each matching entry to show that a notification has occurred. The notifier also sends a signal (using the PID recorded in the table) to awaken the listener from sleep.

This table is not currently used in Greenplum Database.

**Table 3.31** pg\_catalog.pg\_listener

column	type	references	description
relname	name		Notify condition name. (The name need not match any actual relation in the database.)
listenerpid	int4		PID of the server process that created this entry.
notification	int4		Zero if no event is pending for this listener. If an event is pending, the PID of the server process that sent the notification.

## pg\_locks

The view *pg\_locks* provides access to information about the locks held by open transactions within Greenplum Database.

*pg\_locks* contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object may appear many times, if multiple transactions are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (such as tables), individual pages of relations, individual tuples of relations, transaction IDs, and general database objects. Also, the right to extend a relation is represented as a separate lockable object.

**Table 3.32** pg\_catalog.pg\_locks

column	type	references	description
locktype	text		Type of the lockable object: relation, extend, page, tuple, transactionid, object, userlock, resource queue, or advisory
database	oid	<i>pg_database.oid</i>	OID of the database in which the object exists, zero if the object is a shared object, or NULL if the object is a transaction ID
relation	oid	<i>pg_class.oid</i>	OID of the relation, or NULL if the object is not a relation or part of a relation
page	integer		Page number within the relation, or NULL if the object is not a tuple or relation page
tuple	smallint		Tuple number within the page, or NULL if the object is not a tuple
transactionid	xid		ID of a transaction, or NULL if the object is not a transaction ID
classid	oid	<i>pg_class.oid</i>	OID of the system catalog containing the object, or NULL if the object is not a general database object
objid	oid	any OID column	OID of the object within its system catalog, or NULL if the object is not a general database object
objsubid	smallint		For a table column, this is the column number (the <i>classid</i> and <i>objid</i> refer to the table itself). For all other object types, this column is zero. NULL if the object is not a general database object
transaction	xid		ID of the transaction that is holding or awaiting this lock

**Table 3.32** pg\_catalog.pg\_locks

column	type	references	description
pid	integer		Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction
mode	text		Name of the lock mode held or desired by this process
granted	boolean		True if lock is held, false if lock is awaited
mppsessionid	integer		The id of the client session associated with this lock.
mppiswriter	boolean		Is the lock held by a writer process?
gp_segment_id	integer		The Greenplum segment id (dbid) where the lock is held.

## pg\_opclass

The *pg\_opclass* system catalog table defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. Note that there can be multiple operator classes for a given data type/access method combination, thus supporting multiple behaviors. The majority of the information defining an operator class is actually not in its *pg\_opclass* row, but in the associated rows in *pg\_amop* and *pg\_amproc*. Those rows are considered to be part of the operator class definition — this is not unlike the way that a relation is defined by a single *pg\_class* row plus associated rows in *pg\_attribute* and other tables.

**Table 3.33** pg\_catalog.pg\_opclass

column	type	references	description
opcamid	oid	<i>pg_am.oid</i>	Index access method operator class is for.
opcname	name		Name of this operator class
opcnamespace	oid	<i>pg_namespace.oid</i>	Namespace of this operator class
opowner	oid	<i>pg_authid.oid</i>	Owner of the operator class
opcintype	oid	<i>pg_type.oid</i>	Data type that the operator class indexes.
opcdefault	boolean		True if this operator class is the default for the data type <i>opcintype</i> .
opckeytype	oid	<i>pg_type.oid</i>	Type of data stored in index, or zero if same as <i>opcintype</i> .

## pg\_namespace

The *pg\_namespace* system catalog table stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

**Table 3.34** pg\_catalog.pg\_namespace

column	type	references	description
nspname	name		Name of the namespace
nspowner	oid	<i>pg_authid.oid</i>	Owner of the namespace
nspacl	aclitem[]		Access privileges as given by GRANT and REVOKE.

## pg\_operator

The *pg\_operator* system catalog table stores information about operators, both built-in and those defined by `CREATE OPERATOR`. Unused column contain zeroes. For example, *oprleft* is zero for a prefix operator.

**Table 3.35** pg\_catalog.pg\_operator

column	type	references	description
oprname	name		Name of the operator.
oprnamespace	oid	<i>pg_namespace.oid</i>	The OID of the namespace that contains this operator.
oprowner	oid	<i>pg_authid.oid</i>	Owner of the operator.
oprkind	char		b = infix (both), l = prefix (left), r = postfix (right)
oprcanhash	boolean		This operator supports hash joins.
oprleft	oid	<i>pg_type.oid</i>	Type of the left operand.
oprright	oid	<i>pg_type.oid</i>	Type of the right operand.
oprresult	oid	<i>pg_type.oid</i>	Type of the result.
oprcom	oid	<i>pg_operator.oid</i>	Commutator of this operator, if any.
oprnegate		<i>pg_operator.oid</i>	Negator of this operator, if any.
oprlsortop	oid	<i>pg_operator.oid</i>	If this operator supports merge joins, the operator that sorts the type of the left-hand operand ( $L < L$ ).
oprrsortop l	oid	<i>pg_operator.oid</i>	If this operator supports merge joins, the operator that sorts the type of the right-hand operand ( $R < R$ ).
oprltcmpop	oid	<i>pg_operator.oid</i>	If this operator supports merge joins, the less-than operator that compares the left and right operand types ( $L < R$ ).
oprgtcmpop	oid	<i>pg_operator.oid</i>	If this operator supports merge joins, the greater-than operator that compares the left and right operand types ( $L > R$ ).
oprcode	regproc	<i>pg_proc.oid</i>	Function that implements this operator.
oprrest	regproc	<i>pg_proc.oid</i>	Restriction selectivity estimation function for this operator.
oprjoin	regproc	<i>pg_proc.oid</i>	Join selectivity estimation function for this operator.

## pg\_partition

The *pg\_partition* system catalog table is used to track partitioned tables and their inheritance level relationships. Each row of *pg\_partition* represents either the level of a partitioned table in the partition hierarchy, or a subpartition template description. The value of the attribute *paristemplate* determines what a particular row represents.

**Table 3.36** pg\_catalog.pg\_partition

column	type	references	description
parrelid	oid	<i>pg_class.oid</i>	The object identifier of the table.
parkind	char		The partition type - R for range or L for list.
parlevel	smallint		The partition level of this row: 0 for the top-level parent table, 1 for the first level under the parent table, 2 for the second level, and so on.
paristemplate	boolean		Whether or not this row represents a subpartition template definition (true) or an actual partitioning level (false).
parnatts	smallint	<i>pg_attribute.oid</i>	The number of attributes that define this level.
paratts	smallint()		An array of the attribute numbers (as in <i>pg_attribute.attnum</i> ) of the attributes that participate in defining this level.
parclass	oidvector	<i>pg_opclass.oid</i>	The operator class identifier(s) of the partition columns.

## pg\_partition\_columns

The *pg\_partition\_columns* system view is used to show the partition key columns of a partitioned table.

**Table 3.37** pg\_catalog.pg\_partition\_columns

column	type	references	description
schemaname	name		The name of the schema the partitioned table is in.
tablename	name		The table name of the top-level parent table.
columnname	name		The name of the partition key column.
partitionlevel	smallint		The level of this subpartition in the hierarchy.
position_in_partition_key	integer		For list partitions you can have a composite (multi-column) partition key. This shows the position of the column in a composite key.

## pg\_partition\_encoding

The *pg\_partition\_encoding* system catalog table describes the available column compression options for a partition template.

**Table 3.38** pg\_catalog.pg\_attribute\_encoding

column	type	modifiers	storage	description
parencoid	oid	not null	plain	
parencattnum	smallint	not null	plain	
parencattoptions	text [ ]		extended	

## pg\_partition\_rule

The *pg\_partition\_rule* system catalog table is used to track partitioned tables, their check constraints, and data containment rules. Each row of *pg\_partition\_rule* represents either a leaf partition (the bottom level partitions that contain data), or a branch partition (a top or mid-level partition that is used to define the partition hierarchy, but does not contain any data).

**Table 3.39** pg\_catalog.pg\_partition\_rule

column	type	references	description
paroid	oid	<i>pg_partition.oid</i>	Row identifier of the partitioning level (from <i>pg_partition</i> ) to which this partition belongs. In the case of a branch partition, the corresponding table (identified by <i>parchildrelid</i> ) is an empty container table. In case of a leaf partition, the table contains the rows for that partition containment rule.
parchildrelid	oid	<i>pg_class.oid</i>	The table identifier of the partition (child table).
parparentrule	oid	<i>pg_partition_rule.paroid</i>	The row identifier of the rule associated with the parent table of this partition.
parname	name		The given name of this partition.
parisdefault	boolean		Whether or not this partition is a default partition.
parruleord	smallint		For range partitioned tables, the rank of this partition on this level of the partition hierarchy.
parrangestartincl	boolean		For range partitioned tables, whether or not the starting value is inclusive.
parrangeendincl	boolean		For range partitioned tables, whether or not the ending value is inclusive.
parrangestart	text		For range partitioned tables, the starting value of the range.
parrangeend	text		For range partitioned tables, the ending value of the range.
parrangeevery	text		For range partitioned tables, the interval value of the EVERY clause.
parlistvalues	text		For list partitioned tables, the list of values assigned to this partition.
parreloptions	text		An array describing the storage characteristics of the particular partition.

## pg\_partition\_templates

The *pg\_partition\_templates* system view is used to show the subpartitions that were created using a subpartition template.

**Table 3.40** pg\_catalog.pg\_partition\_templates

column	type	references	description
schemaname	name		The name of the schema the partitioned table is in.
tablename	name		The table name of the top-level parent table.
partitionname	name		The name of the subpartition (this is the name to use if referring to the partition in an <code>ALTER TABLE</code> command). <code>NULL</code> if the partition was not given a name at create time or generated by an <code>EVERY</code> clause.
partitiontype	text		The type of subpartition (range or list).
partitionlevel	smallint		The level of this subpartition in the hierarchy.
partitionrank	bigint		For range partitions, the rank of the partition compared to other partitions of the same level.
partitionposition	smallint		The rule order position of this subpartition.
partitionlistvalues	text		For list partitions, the list value(s) associated with this subpartition.
partitionrangestart	text		For range partitions, the start value of this subpartition.
partitionstartinclusive	boolean		T if the start value is included in this subpartition. F if it is excluded.
partitionrangeend	text		For range partitions, the end value of this subpartition.
partitionendinclusive	boolean		T if the end value is included in this subpartition. F if it is excluded.
partitioneveryclause	text		The <code>EVERY</code> clause (interval) of this subpartition.
partitionisdefault	boolean		T if this is a default subpartition, otherwise F.
partitionboundary	text		The entire partition specification for this subpartition.

## pg\_partitions

The *pg\_partitions* system view is used to show the structure of a partitioned table.

**Table 3.41** pg\_catalog.pg\_partitions

column	type	references	description
schemaname	name		The name of the schema the partitioned table is in.
tablename	name		The name of the top-level parent table.
partitiontablename	name		The relation name of the partitioned table (this is the table name to use if accessing the partition directly).
partitionname	name		The name of the partition (this is the name to use if referring to the partition in an <code>ALTER TABLE</code> command). <code>NULL</code> if the partition was not given a name at create time or generated by an <code>EVERY</code> clause.
parentpartitiontablename	name		The relation name of the parent table one level up from this partition.
parentpartitionname	name		The given name of the parent table one level up from this partition.
partitiontype	text		The type of partition (range or list).
partitionlevel	smallint		The level of this partition in the hierarchy.
partitionrank	bigint		For range partitions, the rank of the partition compared to other partitions of the same level.
partitionposition	smallint		The rule order position of this partition.
partitionlistvalues	text		For list partitions, the list value(s) associated with this partition.
partitionrangestart	text		For range partitions, the start value of this partition.
partitionstartinclusive	boolean		<code>T</code> if the start value is included in this partition. <code>F</code> if it is excluded.
partitionrangeend	text		For range partitions, the end value of this partition.
partitionendinclusive	boolean		<code>T</code> if the end value is included in this partition. <code>F</code> if it is excluded.
partitioneveryclause	text		The <code>EVERY</code> clause (interval) of this partition.

**Table 3.41** pg\_catalog.pg\_partitions

column	type	references	description
partitionisdefault	boolean		T if this is a default partition, otherwise F.
partitionboundary	text		The entire partition specification for this partition.

## pg\_pltemplate

The *pg\_pltemplate* system catalog table stores template information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details. Unlike most system catalogs, *pg\_pltemplate* is shared across all databases of Greenplum system: there is only one copy of *pg\_pltemplate* per system, not one per database. This allows the information to be accessible in each database as it is needed.

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

**Table 3.42** pg\_catalog.pg\_pltemplate

column	type	references	description
tmplname	name		Name of the language this template is for
tmpltrusted	boolean		True if language is considered trusted
tmplhandler	text		Name of call handler function
tmplvalidator	text		Name of validator function, or NULL if none
tmpllibrary	text		Path of shared library that implements language
tmplacl	aclitem[]		Access privileges for template (not yet implemented).

## pg\_proc

The *pg\_proc* system catalog table stores information about functions (or procedures), both built-in functions and those defined by `CREATE FUNCTION`. The table contains data for aggregate and window functions as well as plain functions. If *proisagg* is true, there should be a matching row in *pg\_aggregate*. If *proiswin* is true, there should be a matching row in *pg\_window*.

For compiled functions, both built-in and dynamically loaded, *prosrc* contains the function's C-language name (link symbol). For all other currently-known language types, *prosrc* contains the function's source text. *probin* is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

**Table 3.43** pg\_catalog.pg\_proc

column	type	references	description
proname	name		Name of the function.
pronamespace	oid	<i>pg_namespace.oid</i>	The OID of the namespace that contains this function.
proowner	oid	<i>pg_authid.oid</i>	Owner of the function.
prolang	oid	<i>pg_language.oid</i>	Implementation language or call interface of this function.
proisagg	boolean		Function is an aggregate function.
prosecdef	boolean		Function is a security definer (for example, a 'setuid' function).
proisstrict	boolean		Function returns NULL if any call argument is NULL. In that case the function will not actually be called at all. Functions that are not strict must be prepared to handle NULL inputs.
proretset	boolean		Function returns a set (multiple values of the specified data type).
provolatile	char		Tells whether the function's result depends only on its input arguments, or is affected by outside factors. <i>i</i> = <i>immutable</i> (always delivers the same result for the same inputs), <i>s</i> = <i>stable</i> (results (for fixed inputs) do not change within a scan), or <i>v</i> = <i>volatile</i> (results may change at any time or functions with side-effects).
pronargs	int2		Number of arguments.
prorettype	oid	<i>pg_type.oid</i>	Data type of the return value.
proiswin	boolean		Function is neither an aggregate nor a scalar function, but a pure window function.

**Table 3.43** pg\_catalog.pg\_proc

column	type	references	description
proargtypes	oidvector	<i>pg_type.oid</i>	An array with the data types of the function arguments. This includes only input arguments (including INOUT arguments), and thus represents the call signature of the function.
proallargtypes	oid[]	<i>pg_type.oid</i>	An array with the data types of the function arguments. This includes all arguments (including OUT and INOUT arguments); however, if all the arguments are IN arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <i>proargtypes</i> is subscripted from 0.
proargmodes	char[]		An array with the modes of the function arguments: i = IN, o = OUT, b = INOUT. If all the arguments are IN arguments, this field will be null. Note that subscripts correspond to positions of <i>proallargtypes</i> not <i>proargtypes</i> .
proargnames	text[]		An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <i>proallargtypes</i> not <i>proargtypes</i> .
prosrc	text		This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.
probin	bytea		Additional information about how to invoke the function. Again, the interpretation is language-specific.
proacl	aclitem[]		Access privileges for the function as given by GRANT/REVOKE.

## pg\_resourcetype

The *pg\_resourcetype* system catalog table contains information about the extended attributes that can be assigned to Greenplum Database resource queues. Each row details an attribute and inherent qualities such as its default setting, whether it is required, and the value to disable it (when allowed).

This table is populated only on the master. This table is defined in the *pg\_global* tablespace, meaning it is globally shared across all databases in the system.

**Table 3.44** pg\_catalog.pg\_resourcetype

column	type	references	description
restypid	smallint		The resource type ID.
resname	name		The name of the resource type.
resrequired	boolean		Whether the resource type is required for a valid resource queue.
reshasdefault	boolean		Whether the resource type has a default value. When true, the default value is specified in <i>reshasdefaultsetting</i> .
rescandisable	boolean		Whether the type can be removed or disabled. When true, the default value is specified in <i>resdisabledsetting</i> .
resdefaultsetting	text		Default setting for the resource type, when applicable.
resdisabledsetting	text		The value that disables this resource type (when allowed).

## pg\_resqueue

The *pg\_resqueue* system catalog table contains information about Greenplum Database resource queues, which are used for the workload management feature. This table is populated only on the master. This table is defined in the *pg\_global* tablespace, meaning it is globally shared across all databases in the system.

**Table 3.45** pg\_catalog.pg\_resqueue

column	type	references	description
rsqname	name		The name of the resource queue.
rsqcountlimit	real		The active query threshold of the resource queue.
rsqcostlimit	real		The query cost threshold of the resource queue.
rsqovercommit	boolean		Allows queries that exceed the cost threshold to run when the system is idle.
rsqignorecostlimit	real		The query cost limit of what is considered a 'small query'. Queries with a cost under this limit will not be queued and run immediately.

## pg\_resqueue\_attributes

The *pg\_resqueue\_attributes* view allows administrators to see the attributes set for a resource queue, such as its active statement limit, query cost limits, and priority.

**Table 3.46** pg\_catalog.pg\_resqueue\_attributes

column	type	references	description
rsqname	name	<i>pg_resqueue.rsqname</i>	The name of the resource queue.
resname	text		The name of the resource queue attribute.
resetting	text		The current value of a resource queue attribute.
restypid	integer		System assigned resource type id.

## pg\_resqueuecapability

The *pg\_resqueuecapability* system catalog table contains information about the extended attributes, or capabilities, of existing Greenplum Database resource queues. Only resource queues that have been assigned an extended capability, such as a priority setting, are recorded in this table. This table is joined to the *pg\_resqueue* table by resource queue object ID, and to the *pg\_resourcetype* table by resource type ID (*restypid*).

This table is populated only on the master. This table is defined in the *pg\_global* tablespace, meaning it is globally shared across all databases in the system.

**Table 3.47** pg\_catalog.pg\_resqueuecapability

column	type	references	description
rsqueueid	oid	pg_resqueue.oid	The object ID of the associated resource queue.
restypid	smallint	pg_resourcetype.res typeid	The resource type, derived from the <a href="#">pg_resourcetype</a> system table.
resetting	opaque type		The specific value set for the capability referenced in this record. Depending on the actual resource type, this value may have different data types.

## pg\_rewrite

The *pg\_rewrite* system catalog table stores rewrite rules for tables and views. *pg\_class.relhasrules* must be true if a table has any rules in this catalog.

**Table 3.48** pg\_catalog.pg\_rewrite

column	type	references	description
rulename	name		Rule name.
ev_class	oid	<i>pg_class.oid</i>	The table this rule is for.
ev_attr	int2		The column this rule is for (currently, always zero to indicate the whole table).
ev_type	char		Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE.
is_instead	boolean		True if the rule is an INSTEAD rule.
ev_qual	text		Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition.
ev_action	text		Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action.

## pg\_roles

The view *pg\_roles* provides access to information about database roles. This is simply a publicly readable view of *pg\_authid* that blanks out the password field. This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

**Table 3.49** pg\_catalog.pg\_roles

column	type	references	description
rolname	name		Role name
rolsuper	bool		Role has superuser privileges
rolinherit	bool		Role automatically inherits privileges of roles it is a member of
rolcreaterole	bool		Role may create more roles
rolcreatedb	bool		Role may create databases
rolcatupdate	bool		Role may update system catalogs directly. (Even a superuser may not do this unless this column is true.)
rolcanlogin	bool		Role may log in. That is, this role can be given as the initial session authorization identifier
rolconnlimit	int4		For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit
rolpassword	text		Not the password (always reads as *****)
rolvaliduntil	timestamptz		Password expiry time (only used for password authentication); NULL if no expiration
rolconfig	text[]		Session defaults for run-time configuration variables
rolresqueue	oid	<i>pg_resqueue.oid</i>	Object ID of the resource queue this role is assigned to.
oid	oid	<i>pg_authid.oid</i>	Object ID of role
rolcreaterextgpdf	bool		Role may create readable external tables that use the gpfdist protocol.
rolcreaterexthttp	bool		Role may create readable external tables that use the gpfdist protocol.
rolcreatewextgpdf	bool		Role may create writable external tables that use the gpfdist protocol.

## pg\_shdepend

The *pg\_shdepend* system catalog table records the dependency relationships between database objects and shared objects, such as roles. This information allows Greenplum Database to ensure that those objects are unreferenced before attempting to delete them. See also *pg\_depend*, which performs a similar function for dependencies involving objects within a single database. Unlike most system catalogs, *pg\_shdepend* is shared across all databases of Greenplum system: there is only one copy of *pg\_shdepend* per system, not one per database.

In all cases, a *pg\_shdepend* entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by *deptype*:

- **SHARED\_DEPENDENCY\_OWNER (o)** — The referenced object (which must be a role) is the owner of the dependent object.
- **SHARED\_DEPENDENCY\_ACL (a)** — The referenced object (which must be a role) is mentioned in the ACL (access control list) of the dependent object.
- **SHARED\_DEPENDENCY\_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

**Table 3.50** pg\_catalog.pg\_shdepend

column	type	references	description
dbid	oid	<i>pg_database.oid</i>	The OID of the database the dependent object is in, or zero for a shared object.
classid	oid	<i>pg_class.oid</i>	The OID of the system catalog the dependent object is in.
objid	oid	any OID column	The OID of the specific dependent object.
objsubid	int4		For a table column, this is the column number. For all other object types, this column is zero.
refclassid	oid	<i>pg_class.oid</i>	The OID of the system catalog the referenced object is in (must be a shared catalog).
refobjid	oid	any OID column	The OID of the specific referenced object.
refobjsubid	int4		For a table column, this is the referenced column number. For all other object types, this column is zero.
deptype	char		A code defining the specific semantics of this dependency relationship.

## pg\_shdescription

The *pg\_shdescription* system catalog table stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. See also *pg\_description*, which performs a similar function for descriptions involving objects within a single database. Unlike most system catalogs, *pg\_shdescription* is shared across all databases of a Greenplum system: there is only one copy of *pg\_shdescription* per system, not one per database.

**Table 3.51** pg\_catalog.pg\_shdescription

column	type	references	description
objoid	oid	any OID column	The OID of the object this description pertains to.
classoid	oid	<i>pg_class.oid</i>	The OID of the system catalog this object appears in
description	text		Arbitrary text that serves as the description of this object.

## pg\_stat\_activity

The view *pg\_stat\_activity* shows one row per server process and details about its associated user session and query. The columns that report data on the current query are available unless the parameter *stats\_command\_string* has been turned off. Furthermore, these columns are only visible if the user examining the view is a superuser or the same as the user owning the process being reported on.

The maximum length of the query text string stored in the column *current\_query* can be controlled with the server configuration parameter *pgstat\_track\_activity\_query\_size*.

**Table 3.52** pg\_catalog.pg\_stat\_activity

column	type	references	description
datid	oid	<i>pg_database.oid</i>	Database OID
datname	name		Database name
procpid	integer		Process ID of the server process
sess_id	integer		Session ID
usesysid	oid	<i>pg_authid.oid</i>	Role OID
username	name		Role name
current_query	text		Current query that process is running
waiting	boolean		True if waiting on a lock, false if not waiting
query_start	timestampz		Time query began execution
backend_start	timestampz		Time backend process was started
client_addr	inet		Client address
client_port	integer		Client port
application_name	text		Client application name
xact_start	timestampz		Transaction start time
waiting_reason	text		Reason the server process is waiting. The value can be: lock replication

## pg\_stat\_last\_operation

The *pg\_stat\_last\_operation* table contains metadata tracking information about database objects (tables, views, etc.).

**Table 3.53** pg\_catalog.pg\_stat\_last\_operation

column	type	references	description
classid	oid	<i>pg_class.oid</i>	OID of the system catalog containing the object.
objid	oid	any OID column	OID of the object within its system catalog.
staactionname	name		The action that was taken on the object.
stasysid	oid	<i>pg_authid.oid</i>	A foreign key to <i>pg_authid.oid</i> .
stausename	name		The name of the role that performed the operation on this object.
stasubtype	text		The type of object operated on or the subclass of operation performed.
statime	timestamp with timezone		The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs.

## pg\_stat\_last\_shoperation

The *pg\_stat\_last\_shoperation* table contains metadata tracking information about global objects (roles, tablespaces, etc.).

**Table 3.54** pg\_catalog.pg\_stat\_last\_shoperation

column	type	references	description
classid	oid	<i>pg_class.oid</i>	OID of the system catalog containing the object.
objid	oid	any OID column	OID of the object within its system catalog.
staactionname	name		The action that was taken on the object.
stasysid	oid		
stausename	name		The name of the role that performed the operation on this object.
stasubtype	text		The type of object operated on or the subclass of operation performed.
statime	timestamp with timezone		The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs.

## pg\_stat\_operations

The view *pg\_stat\_operations* shows details about the last operation performed on a database object (such as a table, index, view or database) or a global object (such as a role).

**Table 3.55** pg\_catalog.pg\_stat\_operations

column	type	references	description
classname	text		The name of the system table in the <i>pg_catalog</i> schema where the record about this object is stored ( <i>pg_class</i> =relations, <i>pg_database</i> =databases, <i>pg_namespace</i> =schemas, <i>pg_authid</i> =roles)
objname	name		The name of the object.
objid	oid		The OID of the object.
schemaname	name		The name of the schema where the object resides.
usestatus	text		The status of the role who performed the last operation on the object ( <i>CURRENT</i> =a currently active role in the system, <i>DROPPED</i> =a role that no longer exists in the system, <i>CHANGED</i> =a role name that exists in the system, but has changed since the last operation was performed).
username	name		The name of the role that performed the operation on this object.
actionname	name		The action that was taken on the object.
subtype	text		The type of object operated on or the subclass of operation performed.
statime	timestampz		The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs.

## pg\_stat\_partition\_operations

The view *pg\_stat\_partition\_operations* shows details about the last operation performed on a partitioned table.

**Table 3.56** pg\_catalog.pg\_stat\_partition\_operations

column	type	references	description
classname	text		The name of the system table in the <i>pg_catalog</i> schema where the record about this object is stored (always <i>pg_class</i> for tables and partitions).
objname	name		The name of the object.
objid	oid		The OID of the object.
schemaname	name		The name of the schema where the object resides.
usestatus	text		The status of the role who performed the last operation on the object ( <i>CURRENT</i> =a currently active role in the system, <i>DROPPED</i> =a role that no longer exists in the system, <i>CHANGED</i> =a role name that exists in the system, but its definition has changed since the last operation was performed).
username	name		The name of the role that performed the operation on this object.
actionname	name		The action that was taken on the object.
subtype	text		The type of object operated on or the subclass of operation performed.
statime	timestampz		The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs.
partitionlevel	smallint		The level of this partition in the hierarchy.
parenttablename	name		The relation name of the parent table one level up from this partition.
parentschemaname	name		The name of the schema where the parent table resides.
parent_relid	oid		The OID of the parent table one level up from this partition.

## pg\_stat\_replication

The *pg\_stat\_replication* view contains metadata of the `walsender` process that is used for Greenplum Database master mirroring.

**Table 3.57** pg\_catalog.pg\_stat\_replication

column	type	references	description
procpid	integer		Process ID of WAL sender backend process.
usesysid	integer		User system ID that runs the WAL sender backend process
username	name		User name that runs WAL sender backend process.
application_name	oid		Client application name.
client_addr	name		Client IP address.
client_port	integer		Client port number.
backend_start	timestamp		Operation start timestamp.
state	text		WAL sender state. The value can be: startup backup catchup streaming
sent_location	text		WAL sender xlog record sent location.
write_location	text		WAL receiver xlog record write location.
flush_location	text		WAL receiver xlog record flush location.
replay_location	text		Standby xlog record replay location.
sync_priority	text		Priority. the value is 1.
sync_state	text		WAL sender synchronization state. The value is sync.

## pg\_statistic

The *pg\_statistic* system catalog table stores statistical data about the contents of the database. Entries are created by *ANALYZE* and subsequently used by the query planner. There is one entry for each table column that has been analyzed. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

*pg\_statistic* also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, *starelid* references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column.

Since different kinds of statistics may be appropriate for different kinds of data, *pg\_statistic* is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in *pg\_statistic*. Everything else is stored in slots, which are groups of associated columns whose content is identified by a code number in one of the slot's columns.

*pg\_statistic* should not be readable by the public, since even statistical information about a table's contents may be considered sensitive (for example: minimum and maximum values of a salary column). *pg\_stats* is a publicly readable view on *pg\_statistic* that only exposes information about those tables that are readable by the current user.

**Table 3.58** pg\_catalog.pg\_statistic

column	type	references	description
starelid	oid	<i>pg_class.oid</i>	The table or index that the described column belongs to.
staattnum	int2	<i>pg_attribute.attnum</i>	The number of the described column.
stanullfrac	float4		The fraction of the column's entries that are null.
stawidth	int4		The average stored width, in bytes, of nonnull entries.
stadistinct	float4		The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a fraction of the number of rows in the table (for example, a column in which values appear about twice on the average could be represented by <i>stadistinct</i> = -0.5). A zero value means the number of distinct values is unknown.
stakindN	int2		A code number indicating the kind of statistics stored in the <i>N</i> th slot of the <i>pg_statistic</i> row.

**Table 3.58** pg\_catalog.pg\_statistic

column	type	references	description
staopN	oid	<i>pg_operator.oid</i>	An operator used to derive the statistics stored in the <i>N</i> th slot. For example, a histogram slot would show the < operator that defines the sort order of the data.
stanumbersN	float4[]		Numerical statistics of the appropriate kind for the <i>N</i> th slot, or NULL if the slot kind does not involve numerical values.
stavaluesN	anyarray		Column data values of the appropriate kind for the <i>N</i> th slot, or NULL if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, so there is no way to define these columns' type more specifically than <i>anyarray</i> .

## pg\_stat\_resqueues

The *pg\_stat\_resqueues* view allows administrators to view metrics about a resource queue's workload over time. To allow statistics to be collected for this view, you must enable the *stats\_queue\_level* server configuration parameter on the Greenplum Database master instance. Enabling the collection of these metrics does incur a small performance penalty, as each statement submitted through a resource queue must be logged in the system catalog tables.

**Table 3.59** pg\_catalog.pg\_stat\_resqueues

column	type	references	description
queueoid	oid		The OID of the resource queue.
queuename	name		The name of the resource queue.
n_queries_exec	bigint		Number of queries submitted for execution from this resource queue.
n_queries_wait	bigint		Number of queries submitted to this resource queue that had to wait before they could execute.
elapsed_exec	bigint		Total elapsed execution time for statements submitted through this resource queue.
elapsed_wait	bigint		Total elapsed time that statements submitted through this resource queue had to wait before they were executed.

## pg\_tablespace

The *pg\_tablespace* system catalog table stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout. Unlike most system catalogs, *pg\_tablespace* is shared across all databases of a Greenplum system: there is only one copy of *pg\_tablespace* per system, not one per database.

**Table 3.60** pg\_catalog.pg\_tablespace

column	type	references	description
spcname	name		Tablespace name.
spcowner	oid	<i>pg_authid.oid</i>	Owner of the tablespace, usually the user who created it.
spcllocation	text[]		Deprecated.
spcacl	aclitem[]		Tablespace access privileges.
spcprilocations	text[]		Deprecated.
spcmrilocations	text[]		Deprecated.
spcfsoid	oid	<i>pg_filespace.oid</i>	The object id of the filespace used by this tablespace. A filespace defines directory locations on the primary, mirror and master segments.

## pg\_trigger

The *pg\_trigger* system catalog table stores triggers on tables.

**Table 3.61** pg\_catalog.pg\_trigger

column	type	references	description
tgrelid	oid	<i>pg_class.oid</i> Note that Greenplum Database does not enforce referential integrity.	The table this trigger is on.
tgname	name		Trigger name (must be unique among triggers of same table).
tgfoid	oid	<i>pg_proc.oid</i> Note that Greenplum Database does not enforce referential integrity.	The function to be called.
tgtype	int2		Bit mask identifying trigger conditions.
tgenabled	boolean		True if trigger is enabled.
tgisconstraint	boolean		True if trigger implements a referential integrity constraint.
tgconstname	name		Referential integrity constraint name.
tgconstrrelid	oid	<i>pg_class.oid</i> Note that Greenplum Database does not enforce referential integrity.	The table referenced by an referential integrity constraint.
tgdeferrable	boolean		True if deferrable.
tginitdeferred	boolean		True if initially deferred.
tgargs	int2		Number of argument strings passed to trigger function.
tgattr	int2vector		Currently unused.
tgargs	bytea		Argument strings to pass to trigger, each NULL-terminated.

## pg\_type

The *pg\_type* system catalog table stores information about data types. Base types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

**Table 3.62** pg\_catalog.pg\_type

column	type	references	description
typname	name		Data type name.
typnamespace	oid	<i>pg_namespace.oid</i>	The OID of the namespace that contains this type.
typowner	oid	<i>pg_authid.oid</i>	Owner of the type.
typlen	int2		For a fixed-size type, <i>typlen</i> is the number of bytes in the internal representation of the type. But for a variable-length type, <i>typlen</i> is negative. -1 indicates a 'varlena' type (one that has a length word), -2 indicates a null-terminated C string.
typbyval	boolean		Determines whether internal routines pass a value of this type by value or by reference. <i>typbyval</i> had better be false if <i>typlen</i> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <i>typbyval</i> can be false even if the length would allow pass-by-value; this is currently true for type <code>float4</code> , for example.
typtype	char		b for a base type, c for a composite type, d for a domain, or p for a pseudo-type.
typisdefined	boolean		True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When false, nothing except the type name, namespace, and OID can be relied on.
typdelim	char		Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.
typrelid	oid	<i>pg_class.oid</i>	If this is a composite type, then this column points to the <i>pg_class</i> entry that defines the corresponding table. (For a free-standing composite type, the <i>pg_class</i> entry does not really represent a table, but it is needed anyway for the type's <i>pg_attribute</i> entries to link to.) Zero for non-composite types.

**Table 3.62** pg\_catalog.pg\_type

column	type	references	description
typelem	oid	<i>pg_type.oid</i>	If not 0 then it identifies another row in <i>pg_type</i> . The current type can then be subscripted like an array yielding values of type <i>typelem</i> . A true array type is variable length ( <i>typelen</i> = -1), but some fixed-length ( <i>typelen</i> > 0) types also have nonzero <i>typelem</i> , for example <i>name</i> and <i>point</i> . If a fixed-length type has a <i>typelem</i> then its internal representation must be some number of values of the <i>typelem</i> data type with no other data. Variable-length array types have a header defined by the array subroutines.
typinput	regproc	<i>pg_proc.oid</i>	Input conversion function (text format).
typoutput	regproc	<i>pg_proc.oid</i>	Output conversion function (text format).
typreceive	regproc	<i>pg_proc.oid</i>	Input conversion function (binary format), or 0 if none.
typsend	regproc	<i>pg_proc.oid</i>	Output conversion function (binary format), or 0 if none.
typanalyze	regproc	<i>pg_proc.oid</i>	Custom ANALYZE function, or 0 to use the standard function.
typalign	char		The alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside Greenplum Database. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are: c = char alignment (no alignment needed). s = short alignment (2 bytes on most machines). i = int alignment (4 bytes on most machines). d = double alignment (8 bytes on many machines, but not all).
typstorage	char		For varlena types (those with <i>typelen</i> = -1) tells if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are: p: Value must always be stored plain. e: Value can be stored in a secondary relation (if relation has one, see <i>pg_class.reltoastrelid</i> ). m: Value can be stored compressed inline. x: Value can be stored compressed inline or stored in secondary storage. Note that m columns can also be moved out to secondary storage, but only as a last resort (e and x columns are moved first).
typnotnull	boolean		Represents a not-null constraint on a type. Used for domains only.

**Table 3.62** pg\_catalog.pg\_type

column	type	references	description
typbasetype	oid	<i>pg_type.oid</i>	Identifies the type that a domain is based on. Zero if this type is not a domain.
typtypmod	int4		Domains use <i>typtypmod</i> to record the <i>typmod</i> to be applied to their base type (-1 if base type does not use a <i>typmod</i> ). -1 if this type is not a domain.
typndims	int4		The number of array dimensions for a domain that is an array (if <i>typbasetype</i> is an array type; the domain's <i>typelem</i> will match the base type's <i>typelem</i> ). Zero for types other than array domains.
typdefaultbin	text		If not null, it is the <code>nodeToString()</code> representation of a default expression for the type. This is only used for domains.
typdefault	text		Null if the type has no associated default value. If not null, <i>typdefault</i> must contain a human-readable version of the default expression represented by <i>typdefaultbin</i> . If <i>typdefaultbin</i> is null and <i>typdefault</i> is not, then <i>typdefault</i> is the external representation of the type's default value, which may be fed to the type's input converter to produce a constant.

---

## pg\_type\_encoding

The *pg\_type\_encoding* system catalog table contains the column storage type information.

**Table 3.63** pg\_catalog.pg\_type\_encoding

column	type	modifiers	storage	description
typeid	oid	not null	plain	Foreign key to pg_attribute
typoptions	text [ ]		extended	The actual options

## pg\_user\_mapping

The *pg\_user\_mapping* catalog stores the mappings from local users to remote users. You must have administrator privileges to view this catalog.

**Table 3.64** pg\_catalog.pg\_user\_mapping

column	type	references	description
umuser	oid	pg_authid.oid	OID of the local role being mapped, 0 if the user mapping is public
umserver	oid	pg_foreign_server.oid	The OID of the foreign server that contains this mapping
umoptions	text [ ]		User mapping specific options, as "keyword=value" strings.

## pg\_window

The *pg\_window* table stores information about window functions. Window functions are often used to compose complex OLAP (online analytical processing) queries. Window functions are applied to partitioned result sets within the scope of a single query expression. A window partition is a subset of rows returned by a query, as defined in a special *OVER()* clause. Typical window functions are *rank*, *dense\_rank*, and *row\_number*. Each entry in *pg\_window* is an extension of an entry in *pg\_proc*. The *pg\_proc* entry carries the window function's name, input and output data types, and other information that is similar to ordinary functions.

**Table 3.65** pg\_catalog.pg\_window

column	type	references	description
winfnoid	regproc	<i>pg_proc.oid</i>	The OID in <i>pg_proc</i> of the window function.
winrequireorder	boolean		The window function requires its window specification to have an <i>ORDER BY</i> clause.
winallowframe	boolean		The window function permits its window specification to have a <i>ROWS</i> or <i>RANGE</i> framing clause.
winpeercount	boolean		The peer group row count is required to compute this window function, so the Window node implementation must 'look ahead' as necessary to make this available in its internal state.
wincount	boolean		The partition row count is required to compute this window function.
winfunc	regproc	<i>pg_proc.oid</i>	The OID in <i>pg_proc</i> of a function to compute the value of an immediate-type window function.
winprefunc	regproc	<i>pg_proc.oid</i>	The OID in <i>pg_proc</i> of a preliminary window function to compute the partial value of a deferred-type window function.
winpretype	oid	<i>pg_type.oid</i>	The OID in <i>pg_type</i> of the preliminary window function's result type.

**Table 3.65** pg\_catalog.pg\_window

column	type	references	description
winfunc	regproc	pg_proc.oid	The OID in <i>pg_proc</i> of a function to compute the final value of a deferred-type window function from the partition row count and the result of <i>winprefunc</i> .
winkind	char		A character indicating membership of the window function in a class of related functions: w - ordinary window functions n - NTILE functions f - FIRST_VALUE functions l - LAST_VALUE functions g - LAG functions d - LEAD functions

## 4. Greenplum Environment Variables

This reference lists and describes the environment variables to set for Greenplum Database. Set these in your user's startup shell profile (such as `~/.bashrc` or `~/.bash_profile`), or in `/etc/profile` if you want to set them for all users.

---

### Required Environment Variables

**Note:** `GPHOME`, `PATH` and `LD_LIBRARY_PATH` can be set by sourcing the `greenplum_path.sh` file from your Greenplum Database installation directory.

#### **GPHOME**

This is the installed location of your Greenplum Database software. For example:

```
GPHOME=/usr/local/greenplum-db-4.1.x.x
```

```
export GPHOME
```

#### **PATH**

Your `PATH` environment variable should point to the location of the Greenplum Database `bin` directory. Solaris users must also add `/usr/sfw/bin` and `/opt/sfw/bin` to their `PATH`. For example:

```
PATH=$GPHOME/bin:$PATH
```

```
PATH=$GPHOME/bin:/usr/local/bin:/usr/sbin:/usr/sfw/bin:/opt/sfw/bin:$PATH
```

```
export PATH
```

#### **LD\_LIBRARY\_PATH**

The `LD_LIBRARY_PATH` environment variable should point to the location of the Greenplum Database/PostgreSQL library files. For Solaris, this also points to the GNU compiler and readline library files as well (readline libraries may be required for Python support on Solaris). For example:

```
LD_LIBRARY_PATH=$GPHOME/lib
```

```
LD_LIBRARY_PATH=$GPHOME/lib:/usr/sfw/lib
```

```
export LD_LIBRARY_PATH
```

#### **MASTER\_DATA\_DIRECTORY**

This should point to the directory created by the `gpinitssystem` utility in the master data directory location. For example:

```
MASTER_DATA_DIRECTORY=/data/master/gpseg-1
```

```
export MASTER_DATA_DIRECTORY
```

---

## Optional Environment Variables

The following are standard PostgreSQL environment variables, which are also recognized in Greenplum Database. You may want to add the connection-related environment variables to your profile for convenience, so you do not have to type so many options on the command line for client connections. Note that these environment variables should be set on the Greenplum Database master host only.

### **PGAPPNAME**

The name of the application that is usually set by an application when it connects to the server. This name is displayed in the activity view and in log entries. The `PGAPPNAME` environmental variable behaves the same as the `application_name` connection parameter. The default value for `application_name` is *psql*. The name cannot be longer than 63 characters.

### **PGDATABASE**

The name of the default database to use when connecting.

### **PGHOST**

The Greenplum Database master host name.

### **PGHOSTADDR**

The numeric IP address of the master host. This can be set instead of or in addition to `PGHOST` to avoid DNS lookup overhead.

### **PGPASSWORD**

The password used if the server demands password authentication. Use of this environment variable is not recommended for security reasons (some operating systems allow non-root users to see process environment variables via `ps`). Instead consider using the `~/.pgpass` file.

### **PGPASSFILE**

The name of the password file to use for lookups. If not set, it defaults to `~/.pgpass`. See the section about [The Password File](#) in the PostgreSQL documentation for more information.

### **PGOPTIONS**

Sets additional configuration parameters for the Greenplum Database master server.

### **PGPORT**

The port number of the Greenplum Database server on the master host. The default port is 5432.

### **PGUSER**

The Greenplum Database user name used to connect.

### **PGDATESTYLE**

Sets the default style of date/time representation for a session. (Equivalent to `SET datestyle TO ....`)

**PGTZ**

Sets the default time zone for a session. (Equivalent to `SET timezone TO ....`)

**PGCLIENTENCODING**

Sets the default client character set encoding for a session. (Equivalent to `SET client_encoding TO ....`)

## 5. The `gp_toolkit` Administrative Schema

Greenplum Database provides an administrative schema called `gp_toolkit` that you can use to query the system catalogs, log files, and operating environment for system status information. The `gp_toolkit` schema contains a number of views that you can access using SQL commands. The `gp_toolkit` schema is accessible to all database users, although some objects may require superuser permissions. For convenience, you may want to add the `gp_toolkit` schema to your schema search path. For example:

```
=> ALTER ROLE myrole SET search_path TO myschema, gp_toolkit;
```

This documentation describes the most useful views in `gp_toolkit`. You may notice other objects (views, functions, and external tables) within the `gp_toolkit` schema that are not described in this documentation (these are supporting objects to the views described in this section).

---

### Checking for Tables that Need Routine Maintenance

The following views can help identify tables that need routine table maintenance (VACUUM and/or ANALYZE).

- [`gp\_bloat\_diag`](#)
- [`gp\_stats\_missing`](#)

The `VACUUM` or `VACUUM FULL` command reclaims disk space occupied by deleted or obsolete rows. Because of the MVCC transaction concurrency model used in Greenplum Database, data rows that are deleted or updated still occupy physical space on disk even though they are not visible to any new transactions. Expired rows increase table size on disk and eventually slow down scans of the table.

The `ANALYZE` command collects column-level statistics needed by the query planner. Greenplum Database uses a cost-based query planner that relies on database statistics. Accurate statistics allow the query planner to better estimate selectivity and the number of rows retrieved by a query operation in order to choose the most efficient query plan.

---

### gp\_bloat\_diag

This view shows tables that have bloat (the actual number of pages on disk exceeds the expected number of pages given the table statistics). Tables that are bloated require a `VACUUM` or a `VACUUM FULL` in order to reclaim disk space occupied by deleted or obsolete rows. This view is accessible to all users, however non-superusers will only be able to see the tables that they have permission to access.

**Table 5.1** *gp\_bloat\_diag* view

Column	Description
bdirelid	Table object id.
bdinspname	Schema name.
bdirelname	Table name.
bdirelpages	Actual number of pages on disk.
bdiexppages	Expected number of pages given the table data.
bdidiag	Bloat diagnostic message.

---

### gp\_stats\_missing

This view shows tables that do not have statistics and therefore may require an `ANALYZE` be run on the table.

**Table 5.2** *gp\_stats\_missing* view

Column	Description
smischema	Schema name.
smitable	Table name.
smisize	Does this table have statistics? False if the table does not have row count and row sizing statistics recorded in the system catalog, which may indicate that the table needs to be analyzed. This will also be false if the table does not contain any rows. For example, the parent tables of partitioned tables are always empty and will always return a false result.
smicols	Number of columns in the table.
smirecs	Number of rows in the table.

---

## Checking for Locks

When a transaction accesses a relation (such as a table), it acquires a lock. Depending on the type of lock acquired, subsequent transactions may have to wait before they can access the same relation. For more information on the types of locks, see the *Greenplum Database Database Administrator Guide*. Greenplum Database resource queues (used for workload management) also use locks to control the admission of queries into the system.

The *gp\_locks\_\** family of views can help diagnose queries and sessions that are waiting to access an object due to a lock.

- [\*gp\\_locks\\_on\\_relation\*](#)
- [\*gp\\_locks\\_on\\_resqueue\*](#)

## **gp\_locks\_on\_relation**

This view shows any locks currently being held on a relation, and the associated session information about the query associated with the lock. For more information on the types of locks, see the *Greenplum Database Database Administrator Guide*. This view is accessible to all users, however non-superusers will only be able to see the locks for relations that they have permission to access.

**Table 5.3** *gp\_locks\_on\_relation* view

Column	Description
lorlocktype	Type of the lockable object: relation, extend, page, tuple, transactionid, object, userlock, resource queue, or advisory
lordatabase	Object ID of the database in which the object exists, zero if the object is a shared object.
lorrelname	The name of the relation.
lorrelation	The object ID of the relation.
lortransaction	The transaction ID that is affected by the lock.
lorpid	Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction.
lormode	Name of the lock mode held or desired by this process.
lorgranted	Displays whether the lock is granted (true) or not granted (false).
lorcurrentquery	The current query in the session.

## **gp\_locks\_on\_resqueue**

This view shows any locks currently being held on a resource queue, and the associated session information about the query associated with the lock. This view is accessible to all users, however non-superusers will only be able to see the locks associated with their own sessions.

**Table 5.4** *gp\_locks\_on\_resqueue* view

Column	Description
lorusername	Name of the user executing the session.
lorrysqueue	The resource queue name.
lorlocktype	Type of the lockable object: resource queue
lorobjid	The ID of the locked transaction.
lortransaction	The ID of the transaction that is affected by the lock.

**Table 5.4** *gp\_locks\_on\_resqueue* view

Column	Description
lorpid	The process ID of the transaction that is affected by the lock.
lormode	The name of the lock mode held or desired by this process.
lorgranted	Displays whether the lock is granted (true) or not granted (false).
lorwaiting	Displays whether or not the session is waiting.

## Checking Append-Optimized Tables

The *gp\_toolkit* schema includes a set of diagnostic functions you can use to investigate the state of append-optimized tables.

When an append-optimized table (or column-oriented append-optimized table) is created, another table is implicitly created, containing metadata about the current state of the table. The metadata includes information such as the number of records in each of the table's segments.

Append-optimized tables may have non-visible rows—rows that have been updated or deleted, but remain in storage until the table is compacted using *VACUUM*. The hidden rows are tracked using an auxiliary visibility map table, or *visimap*.

The following functions let you access the metadata for append-optimized and column-oriented tables and view non-visible rows. Some of the functions have two versions: one that takes the *oid* of the table, and one that takes the name of the table. The latter version has “\_name” appended to the function name.

---

### **`__gp_aseg_name('table_name')`**

This function returns metadata information contained in the append-optimized table's on-disk segment file.

**Table 5.5** *\_\_gp\_aseg\_name* output table

Column	Description
segno	The file segment number.
eof	The effective end of file for this file segment.
tupcount	The total number of tuples in the segment, including invisible tuples.
varblockcount	The total number of varblocks in the file segment.
eof_uncompressed	The end of file if the file segment were uncompressed.
modcount	The number of data modification operations.
state	The state of the file segment. Indicates if the segment is active or ready to be dropped after compaction.

---

**\_\_gp\_aoseg\_history(*oid*)**

This function returns metadata information contained in the append-optimized table's on-disk segment file. It displays all different versions (heap tuples) of the aoseg meta information. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the oid of the append-optimized table.

Call `__gp_aoseg_history_name('table_name')` to get the same result with the table name as an argument.

**Table 5.6** `__gp_aoseg_history` output table

Column	Description
gp_tid	The id of the tuple.
gp_xmin	The id of the earliest transaction.
gp_xmin_status	Status of the <i>gp_xmin</i> transaction.
gp_xmin_commit_	The commit distribution id of the <i>gp_xmin</i> transaction.
gp_xmax	The id of the latest transaction.
gp_xmax_status	The status of the latest transaction.
gp_xmax_commit_	The commit distribution id of the <i>gp_xmax</i> transaction.
gp_command_id	The id of the query command.
gp_infomask	A bitmap containing state information.
gp_update_tid	The ID of the newer tuple if the row is updated.
gp_visibility	The tuple visibility status.
segno	The number of the segment in the segment file.
tupcount	The number of tuples, including hidden tuples.
eof	The effective end of file for the segment.
eof_uncompressed	The end of file for the segment if data were uncompressed.
modcount	A count of data modifications.
state	The status of the segment.

---

**\_\_gp\_aocsseg(*oid*)**

This function returns metadata information contained in a column-oriented append-optimized table's on-disk segment file, excluding non-visible rows. Each row describes a segment for a column in the table.

The input argument is the oid of a column-oriented append-optimized table. Call as `__gp_aocsseg_name('table_name')` to get the same result with the table name as an argument.

**Table 5.7** `__gp_aocsseg(oid)` output table

Column	Description
gp_tid	The table id.
segno	The segment number.
column_num	The column number.
physical_segno	The number of the segment in the segment file.
tupcount	The number of rows in the segment, excluding hidden tuples.
eof	The effective end of file for the segment.
eof_uncompressed	The end of file for the segment if the data were uncompressed.
modcount	A count of data modification operations for the segment.
state	The status of the segment.

---

### **`__gp_aocsseg_history(oid)`**

This function returns metadata information contained in a column-oriented append-optimized table's on-disk segment file. Each row describes a segment for a column in the table. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the oid of a column-oriented append-optimized table. Call as `__gp_aocsseg_history_name('table_name')` to get the same result with the table name as argument.

**Table 5.8** `__gp_aocsseg_history` output table

Column	Description
gp_tid	The oid of the tuple.
gp_xmin	The earliest transaction.
gp_xmin_status	The status of the <i>gp_xmin</i> transaction.
gp_xmin_	Text representation of <i>gp_xmin</i> .
gp_xmax	The latest transaction.
gp_xmax_status	The status of the <i>gp_xmax</i> transaction.
gp_xmax_	Text representation of <i>gp_max</i> .
gp_command_id	ID of the command operating on the tuple.
gp_infomask	A bitmap containing state information.
gp_update_tid	The ID of the newer tuple if the row is updated.
gp_visibility	The tuple visibility status.
segno	The segment number in the segment file.

**Table 5.8** `__gp_aocsseg_history` output table

Column	Description
column_num	The column number.
physical_segno	The segment containing data for the column.
tupcount	The total number of tuples in the segment.
eof	The effective end of file for the segment.
eof_uncompressed	The end of file for the segment if the data were uncompressed.
modcount	A count of the data modification operations.
state	The state of the segment.

---

**`__gp_aovisimap(oid)`**

This function returns the tuple id, the segment file, and the row number of each non-visible tuple according to the visibility map.

The input argument is the oid of an append-optimized table.

Use `__gp_aovisimap_name('table_name')` to get the same result with the table name as argument.

**Table 5.9**

Column	Description
tid	The tuple id.
segno	The number of the segment file.
row_num	The row number of a row that has been deleted or updated.

---

**`__gp_aovisimap_hidden_info(oid)`**

This function returns the numbers of hidden and visible tuples in the segment files for an append-optimized table.

The input argument is the oid of the append-optimized table.

Call `__gp_aovisimap_hidden_info_name('table_name')` to get the same result with a table name argument.

**Table 5.10**

Column	Description
segno	The number of the segment file.
hidden_tupcount	The number of hidden tuples in the segment file.
total_tupcount	The total number of tuples in the segment file.

---

**\_\_gp\_aovisimap\_entry(*oid*)**

This function returns information about each visibility map entry for the table.

The input argument is the oid of an append-optimized table.

Call `__gp_aovisimap_entry_name('table_name')` to get the same result with a table name argument.

**Table 5.11** `__gp_aovisimap_entry` output table

Column	Description
segno	Segment number of the visibility map entry.
first_row_num	The first row number of the entry.
hidden_tupcount	The number of hidden tuples in the entry.
bitmap	A text representation of the visibility bitmap.

---

## Viewing Greenplum Database Server Log Files

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) keeps its own server log files. The `gp_log_*` family of views allows you to issue SQL queries against the server log files to find particular entries of interest. The use of these views require superuser permissions.

- [\*gp\\_log\\_command\\_timings\*](#)
- [\*gp\\_log\\_database\*](#)
- [\*gp\\_log\\_master\\_concise\*](#)
- [\*gp\\_log\\_system\*](#)

---

**gp\_log\_command\_timings**

This view uses an external table to read the log files on the master and report the execution time of SQL commands executed in a database session. The use of this view requires superuser permissions.

**Table 5.12** `gp_log_command_timings` view

Column	Description
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logdatabase	The name of the database.
loguser	The name of the database user.
logpid	The process id (prefixed with "p").
logtimemin	The time of the first log message for this command.
logtimemax	The time of the last log message for this command.
logduration	Statement duration from start to end time.

## gp\_log\_database

This view uses an external table to read the server log files of the entire Greenplum system (master, segments, and mirrors) and lists log entries associated with the current database. Associated log entries can be identified by the session id (*logsession*) and command id (*logcmdcount*). The use of this view requires superuser permissions.

**Table 5.13** *gp\_log\_database* view

Column	Description
logtime	The timestamp of the log message.
loguser	The name of the database user.
logdatabase	The name of the database.
logpid	The associated process id (prefixed with "p").
logthread	The associated thread count (prefixed with "th").
loghost	The segment or master host name.
logport	The segment or master port.
logsessiontime	Time session connection was opened.
logtransaction	Global transaction id.
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logsegment	The segment content identifier (prefixed with "seg" for primary or "mir" for mirror. The master always has a content id of -1).
logslice	The slice id (portion of the query plan being executed).
logdistxact	Distributed transaction id.
loglocalxact	Local transaction id.
logsubxact	Subtransaction id.
logseverity	LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.
logstate	SQL state code associated with the log message.
logmessage	Log or error message text.
logdetail	Detail message text associated with an error message.
loghint	Hint message text associated with an error message.
logquery	The internally-generated query text.
logquerypos	The cursor index into the internally-generated query text.
logcontext	The context in which this message gets generated.
logdebug	Query string with full detail for debugging.
logcursorpos	The cursor index into the query string.
logfunction	The function in which this message is generated.
logfile	The log file in which this message is generated.

**Table 5.13** *gp\_log\_database* view

Column	Description
logline	The line in the log file in which this message is generated.
logstack	Full text of the stack trace associated with this message.

---

### gp\_log\_master\_concise

This view uses an external table to read a subset of the log fields from the master log file. The use of this view requires superuser permissions.

**Table 5.14** *gp\_log\_master\_concise* view

Column	Description
logtime	The timestamp of the log message.
logdatabase	The name of the database.
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logmessage	Log or error message text.

---

### gp\_log\_system

This view uses an external table to read the server log files of the entire Greenplum system (master, segments, and mirrors) and lists all log entries. Associated log entries can be identified by the session id (*logsession*) and command id (*logcmdcount*). The use of this view requires superuser permissions.

**Table 5.15** *gp\_log\_system* view

Column	Description
logtime	The timestamp of the log message.
loguser	The name of the database user.
logdatabase	The name of the database.
logpid	The associated process id (prefixed with "p").
logthread	The associated thread count (prefixed with "th").
loghost	The segment or master host name.
logport	The segment or master port.
logsessiontime	Time session connection was opened.
logtransaction	Global transaction id.
logsession	The session identifier (prefixed with "con").
logcmdcount	The command number within a session (prefixed with "cmd").
logsegment	The segment content identifier (prefixed with "seg" for primary or "mir" for mirror. The master always has a content id of -1).

**Table 5.15** *gp\_log\_system* view

Column	Description
logslice	The slice id (portion of the query plan being executed).
logdistxact	Distributed transaction id.
loglocalxact	Local transaction id.
logsubxact	Subtransaction id.
logseverity	LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.
logstate	SQL state code associated with the log message.
logmessage	Log or error message text.
logdetail	Detail message text associated with an error message.
loghint	Hint message text associated with an error message.
logquery	The internally-generated query text.
logquerypos	The cursor index into the internally-generated query text.
logcontext	The context in which this message gets generated.
logdebug	Query string with full detail for debugging.
logcursorpos	The cursor index into the query string.
logfunction	The function in which this message is generated.
logfile	The log file in which this message is generated.
logline	The line in the log file in which this message is generated.
logstack	Full text of the stack trace associated with this message.

---

## Checking Server Configuration Files

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) has its own server configuration file (`postgresql.conf`). The following *gp\_toolkit* objects can be used to check parameter settings across all primary `postgresql.conf` files in the system:

- *gp\_param\_setting('parameter\_name')*
- *gp\_param\_settings\_seg\_value\_diffs*

**gp\_param\_setting('parameter\_name')**

This function takes the name of a server configuration parameter and returns the `postgresql.conf` value for the master and each active segment. This function is accessible to all users.

**Table 5.16** *gp\_param\_setting('parameter\_name')* function

Column	Description
paramsegment	The segment content id (only active segments are shown). The master content id is always -1.
paramname	The name of the parameter.
paramvalue	The value of the parameter.

**Example:**

```
SELECT * FROM gp_param_setting('max_connections');
```

**gp\_param\_settings\_seg\_value\_diffs**

Server configuration parameters that are classified as *local* parameters (meaning each segment gets the parameter value from its own `postgresql.conf` file), should be set identically on all segments. This view shows local parameter settings that are inconsistent. Parameters that are supposed to have different values (such as `port`) are not included. This view is accessible to all users.

**Table 5.17** *gp\_param\_settings\_seg\_value\_diffs* view

Column	Description
psdname	The name of the parameter.
psdvalue	The value of the parameter.
psdcount	The number of segments that have this value.

## Checking for Failed Segments

The *gp\_pgdatabase\_invalid* view can be used to check for down segments.

**gp\_pgdatabase\_invalid**

This view shows information about segments that are marked as down in the system catalog. This view is accessible to all users.

**Table 5.18** *gp\_pgdatabase\_invalid* view

Column	Description
pgdbidbid	The segment dbid. Every segment has a unique dbid.
pgdbisprimary	Is the segment currently acting as the primary (active) segment? (t or f)

**Table 5.18** *gp\_pgdatabase\_invalid* view

Column	Description
pgdbcontent	The content id of this segment. A primary and mirror will have the same content id.
pgdbvalid	Is this segment up and valid? (t or f)
pgdbdefinedprimary	Was this segment assigned the role of primary at system initialization time? (t or f)

## Checking Resource Queue Activity and Status

The purpose of resource queues is to limit the number of active queries in the system at any given time in order to avoid exhausting system resources such as memory, CPU, and disk I/O. All database users are assigned to a resource queue, and every statement submitted by a user is first evaluated against the resource queue limits before it can run. The *gp\_resq\_\** family of views can be used to check the status of statements currently submitted to the system through their respective resource queue. Note that statements issued by superusers are exempt from resource queuing.

- [\*gp\\_resq\\_activity\*](#)
- [\*gp\\_resq\\_activity\\_by\\_queue\*](#)
- [\*gp\\_resq\\_priority\\_statement\*](#)
- [\*gp\\_resq\\_role\*](#)
- [\*gp\\_resqueue\\_status\*](#)

### gp\_resq\_activity

For the resource queues that have active workload, this view shows one row for each active statement submitted through a resource queue. This view is accessible to all users.

**Table 5.19** *gp\_resq\_activity* view

Column	Description
resqprocpid	Process ID assigned to this statement (on the master).
resqrole	User name.
resqoid	Resource queue object id.
resqname	Resource queue name.
resqstart	Time statement was issued to the system.
resqstatus	Status of statement: running, waiting or cancelled.

---

**gp\_resq\_activity\_by\_queue**

For the resource queues that have active workload, this view shows a summary of queue activity. This view is accessible to all users.

**Table 5.20** *gp\_resq\_activity\_by\_queue* Column

Column	Description
resqoid	Resource queue object id.
resqname	Resource queue name.
resqlast	Time of the last statement issued to the queue.
resqstatus	Status of last statement: running, waiting or cancelled.
resqtotal	Total statements in this queue.

---

**gp\_resq\_priority\_statement**

This view shows the resource queue priority, session ID, and other information for all statements currently running in the Greenplum Database system. This view is accessible to all users.

**Table 5.21** *gp\_resq\_priority\_statement* view

Column	Description
rqpdbname	The database name that the session is connected to.
rqpusername	The user who issued the statement.
rqpsession	The session ID.
rqpcommand	The number of the statement within this session (the command id and session id uniquely identify a statement).
rqppriority	The resource queue priority for this statement (MAX, HIGH, MEDIUM, LOW).
rqpweight	An integer value associated with the priority of this statement.
rqpquery	The query text of the statement.

---

**gp\_resq\_role**

This view shows the resource queues associated with a role. This view is accessible to all users.

**Table 5.22** *gp\_resq\_role* view

Column	Description
rrrolname	Role (user) name.
rrrsqname	The resource queue name assigned to this role. If a role has not been explicitly assigned to a resource queue, it will be in the default resource queue ( <i>pg_default</i> ).

## gp\_resqueue\_status

This view allows administrators to see status and activity for a workload management resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

**Table 5.23** gp\_resqueue\_status view

Column	Description
queueid	The ID of the resource queue.
rsqname	The name of the resource queue.
rsqcountlimit	The active query threshold of the resource queue. A value of -1 means no limit.
rsqcountvalue	The number of active query slots currently being used in the resource queue.
rsqcostlimit	The query cost threshold of the resource queue. A value of -1 means no limit.
rsqcostvalue	The total cost of all statements currently in the resource queue.
rsqmemorylimit	The memory limit for the resource queue.
rsqmemoryvalue	The total memory used by all statements currently in the resource queue.
rsqwaiters	The number of statements currently waiting in the resource queue.
rsqholders	The number of statements currently running on the system from this resource queue.

## Checking Query Disk Spill Space Usage

The *gp\_workfile\_\** views show information about all the queries that are currently using disk spill space. Greenplum Database creates work files on disk if it does not have sufficient memory to execute the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the Greenplum Database configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

- [gp\\_workfile\\_entries](#)
- [gp\\_workfile\\_usage\\_per\\_query](#)
- [gp\\_workfile\\_usage\\_per\\_segment](#)

## gp\_workfile\_entries

This view contains one row for each operator using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

**Table 5.24** gp\_workfile\_entries

column	type	references	description
command_cnt	integer		Command ID of the query.
content	smallint		The content identifier for a segment instance.
current_query	text		Current query that the process is running.
datname	name		Greenplum database name.
directory	text		Path to the work file.
optype	text		The query operator type that created the work file.
procpid	integer		Process ID of the server process.
sess_id	integer		Session ID.
size	bigint		The size of the work file in bytes.
numfiles	bigint		The number of files created.
slice	smallint		The query plan slice. The portion of the query plan that is being executed.
state	text		The state of the query that created the work file.
username	name		Role name.
workmem	integer		The amount of memory allocated to the operator in KB.

---

**gp\_workfile\_usage\_per\_query**

This view contains one row for each query using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

**Table 5.25** gp\_workfile\_usage\_per\_query

column	type	references	description
command_cnt	integer		Command ID of the query.
content	smallint		The content identifier for a segment instance.
current_query	text		Current query that the process is running.
datname	name		Greenplum database name.
procpid	integer		Process ID of the server process.
sess_id	integer		Session ID.
size	bigint		The size of the work file in bytes.
numfiles	bigint		The number of files created.
state	text		The state of the query that created the work file.
username	name		Role name.

---

**gp\_workfile\_usage\_per\_segment**

This view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

**Table 5.26** gp\_workfile\_usage\_per\_segment

column	type	references	description
content	smallint		The content identifier for a segment instance.
size	bigint		The total size of the work files on a segment.
numfiles	bigint		The number of files created.

## Viewing Users and Groups (Roles)

It is frequently convenient to group users (roles) together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In Greenplum Database this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.

The *gp\_roles\_assigned* view can be used to see all of the roles in the system, and their assigned members (if the role is also a group role).

### **gp\_roles\_assigned**

This view shows all of the roles in the system, and their assigned members (if the role is also a group role). This view is accessible to all users.

**Table 5.27** *gp\_roles\_assigned* view

Column	Description
raroleid	The role object ID. If this role has members (users), it is considered a <i>group</i> role.
rarolename	The role (user or group) name.
ramemberid	The role object ID of the role that is a member of this role.
ramembername	Name of the role that is a member of this role.

## Checking Database Object Sizes and Disk Space

The *gp\_size\_\** family of views can be used to determine the disk space usage for a distributed Greenplum database, schema, table, or index. The following views calculate the total size of an object across all primary segments (mirrors are not included in the size calculations).

- *gp\_size\_of\_all\_table\_indexes*
- *gp\_size\_of\_database*
- *gp\_size\_of\_index*
- *gp\_size\_of\_partition\_and\_indexes\_disk*
- *gp\_size\_of\_schema\_disk*
- *gp\_size\_of\_table\_and\_indexes\_disk*
- *gp\_size\_of\_table\_and\_indexes\_licensing*
- *gp\_size\_of\_table\_disk*
- *gp\_size\_of\_table\_uncompressed*
- *gp\_disk\_free*

The table and index sizing views list the relation by object ID (not by name). To check the size of a table or index by name, you must look up the relation name (*relname*) in the *pg\_class* table. For example:

```

SELECT relname as name, sotdsize as size, sotdtoastsize as
toast, sotdadditionalsize as other
FROM gp_size_of_table_disk as sotd, pg_class
WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;

```

---

### gp\_size\_of\_all\_table\_indexes

This view shows the total size of all indexes for a table. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

**Table 5.28** *gp\_size\_of\_all\_table\_indexes* view

Column	Description
soatoid	The object ID of the table
soatize	The total size of all table indexes in bytes
soatischemaname	The schema name
soatitablename	The table name

---

### gp\_size\_of\_database

This view shows the total size of a database. This view is accessible to all users, however non-superusers will only be able to see databases that they have permission to access.

**Table 5.29** *gp\_size\_of\_database* view

Column	Description
sodddatname	The name of the database
sodddatsize	The size of the database in bytes

---

### gp\_size\_of\_index

This view shows the total size of an index. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

**Table 5.30** *gp\_size\_of\_index* view

Column	Description
soioid	The object ID of the index
soitableoid	The object ID of the table to which the index belongs
soisize	The size of the index in bytes
soiindexschename	The name of the index schema
soiindexname	The name of the index

**Table 5.30** *gp\_size\_of\_index* view

Column	Description
soitableschemaname	The name of the table schema
soitablename	The name of the table

---

### **gp\_size\_of\_partition\_and\_indexes\_disk**

This view shows the size on disk of partitioned child tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access..

**Table 5.31** *gp\_size\_of\_partition\_and\_indexes\_disk* view

Column	Description
sopaidparentoid	The object ID of the parent table
sopaidpartitionoid	The object ID of the partition table
sopaidpartitiontablesize	The partition table size in bytes
sopaidpartitionindexessize	The total size of all indexes on this partition
Sopaidparentschemaname	The name of the parent schema
Sopaidparenttablename	The name of the parent table
Sopaidpartitionschemaname	The name of the partition schema
sopaidpartitiontablename	The name of the partition table

---

### **gp\_size\_of\_schema\_disk**

This view shows schema sizes for the public schema and the user-created schemas in the current database. This view is accessible to all users, however non-superusers will be able to see only the schemas that they have permission to access.

**Table 5.32** *gp\_size\_of\_schema\_disk* view

Column	Description
sosdnsp	The name of the schema
sosdschematablesize	The total size of tables in the schema in bytes
sosdschemaidxsize	The total size of indexes in the schema in bytes

**gp\_size\_of\_table\_and\_indexes\_disk**

This view shows the size on disk of tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

**Table 5.33** *gp\_size\_of\_table\_and\_indexes\_disk* view

Column	Description
sotaidoid	The object ID of the parent table
sotaidtablesize	The disk size of the table
sotaididxsize	The total size of all indexes on the table
sotaid schemaname	The name of the schema
sotaidtablename	The name of the table

**gp\_size\_of\_table\_and\_indexes\_licensing**

This view shows the total size of tables and their indexes for licensing purposes. The use of this view requires superuser permissions.

**Table 5.34** *gp\_size\_of\_table\_and\_indexes\_licensing* view

Column	Description
sotailoid	The object ID of the table
sotailtablesize disk	The total disk size of the table
sotailtablesize uncompressed	If the table is a compressed append-optimized table, shows the uncompressed table size in bytes.
sotailindexessize	The total size of all indexes in the table
sotailschemaname	The schema name
sotailtablename	The table name

**gp\_size\_of\_table\_disk**

This view shows the size of a table on disk. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

**Table 5.35** *gp\_size\_of\_table\_disk* view

Column	Description
sotdoid	The object ID of the table
sotdsize	The total size of the table in bytes (main relation, plus oversized (toast) attributes, plus additional storage objects for AO tables).
sotdtoastsize	The size of the TOAST table (oversized attribute storage), if there is one.

**Table 5.35** *gp\_size\_of\_table\_disk* view

Column	Description
sotdadditionalsize	Reflects the segment and block directory table sizes for append-optimized (AO) tables.
sotdschemaname	The schema name
sotdtablename	The table name

---

### **gp\_size\_of\_table\_uncompressed**

This view shows the uncompressed table size for append-optimized (AO) tables. Otherwise, the table size on disk is shown. The use of this view requires superuser permissions.

**Table 5.36** *gp\_size\_of\_table\_uncompressed* view

Column	Description
sotuid	The object ID of the table
sotusize	The uncompressed size of the table in bytes if it is a compressed AO table. Otherwise, the table size on disk.
sotuschemaname	The schema name
sotutablename	The table name

---

### **gp\_disk\_free**

This external table runs the `df` (disk free) command on the active segment hosts and reports back the results. Inactive mirrors are not included in the calculation. The use of this external table requires superuser permissions.

**Table 5.37** *gp\_disk\_free* external table

Column	Description
dfsegment	The content id of the segment (only active segments are shown)
dfhostname	The hostname of the segment host
dfdevice	The device name
dfspace	Free disk space in the segment file system in kilobytes

---

## **Checking for Uneven Data Distribution**

All tables in Greenplum Database are distributed, meaning their data is divided across all of the segments in the system. If the data is not distributed evenly, then query processing performance may suffer. The following views can help diagnose if a table has uneven data distribution:

- [\*gp\\_skew\\_coefficients\*](#)
- [\*gp\\_skew\\_idle\\_fractions\*](#)

## gp\_skew\_coefficients

This view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

**Table 5.38** *gp\_skew\_coefficients* view

Column	Description
skcoid	The object id of the table.
skcnamespace	The namespace where the table is defined.
skcrelname	The table name.
skccoeff	The coefficient of variation (CV) is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.

## gp\_skew\_idle\_fractions

This view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of processing data skew. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

**Table 5.39** *gp\_skew\_idle\_fractions* view

Column	Description
sifoid	The object id of the table.
sifnamespace	The namespace where the table is defined.
sifrelname	The table name.
siffraction	The percentage of the system that is idle during a table scan, which is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

# 6. Greenplum Database Data Types

Greenplum Database has a rich set of native data types available to users. Users may also define new data types using the `CREATE TYPE` command. This reference shows all of the built-in data types. In addition to the types listed here, there are also some internally used data types, such as *oid* (object identifier), but those are not documented in this guide.

The following data types are specified by SQL: *bit*, *bit varying*, *boolean*, *character varying*, *varchar*, *character*, *char*, *date*, *double precision*, *integer*, *interval*, *numeric*, *decimal*, *real*, *smallint*, *time* (with or without time zone), and *timestamp* (with or without time zone).

Each data type has an external representation determined by its input and output functions. Many of the built-in types have obvious external formats. However, several types are either unique to PostgreSQL (and Greenplum Database), such as geometric paths, or have several possibilities for formats, such as the date and time types. Some of the input and output functions are not invertible. That is, the result of an output function may lose accuracy when compared to the original input.

**Table 6.1** Greenplum Database Built-in Data Types

Name <sup>1</sup>	Alias	Size	Range	Description
bigint	int8	8 bytes	-9223372036854775808 to 9223372036854775807	large range integer
bigserial	serial8	8 bytes	1 to 9223372036854775807	large autoincrementing integer
bit [ (n) ]		<i>n</i> bits	<a href="#">bit string constant</a>	fixed-length bit string
bit varying [ (n) ]	varbit	actual number of bits	<a href="#">bit string constant</a>	variable-length bit string
boolean	bool	1 byte	true/false, t/f, yes/no, y/n, 1/0	logical boolean (true/false)
box		32 bytes	((x1,y1),(x2,y2))	rectangular box in the plane - not allowed in distribution key columns.
bytea		1 byte + <i>binary string</i>	sequence of <a href="#">octets</a>	variable-length binary string
character [ (n) ]	char [ (n) ]	1 byte + <i>n</i>	strings up to <i>n</i> characters in length	fixed-length, blank padded
character varying [ (n) ]	varchar [ (n) ]	1 byte + <i>string size</i>	strings up to <i>n</i> characters in length	variable-length with limit
cidr		12 or 24 bytes		IPv4 and IPv6 networks

**Table 6.1** Greenplum Database Built-in Data Types

Name <sup>1</sup>	Alias	Size	Range	Description
circle		24 bytes	<(x,y),r> (center and radius)	circle in the plane - not allowed in distribution key columns.
date		4 bytes	4713 BC - 294,277 AD	calendar date (year, month, day)
decimal [ (p, s) ]	numeric [ (p, s) ]	variable	no limit	user-specified precision, exact
double precision	float8 float	8 bytes	15 decimal digits precision	variable-precision, inexact
inet		12 or 24 bytes		IPv4 and IPv6 hosts and networks
integer	int, int4	4 bytes	-2147483648 to +2147483647	usual choice for integer
interval [ (p) ]		12 bytes	-178000000 years - 178000000 years	time span
lseg		32 bytes	((x1,y1),(x2,y2))	line segment in the plane - not allowed in distribution key columns.
macaddr		6 bytes		MAC addresses
money		4 bytes	-21474836.48 to +21474836.47	currency amount
path		16+16n bytes	[(x1,y1),...]	geometric path in the plane - not allowed in distribution key columns.
point		16 bytes	(x,y)	geometric point in the plane - not allowed in distribution key columns.
polygon		40+16n bytes	((x1,y1),...)	closed geometric path in the plane - not allowed in distribution key columns.
real	float4	4 bytes	6 decimal digits precision	variable-precision, inexact
serial	serial4	4 bytes	1 to 2147483647	autoincrementing integer
smallint	int2	2 bytes	-32768 to +32767	small range integer
text		1 byte + <i>string size</i>	strings of any length	variable unlimited length
time [ (p) ] [ without time zone ]		8 bytes	00:00:00[.000000] - 24:00:00[.000000]	time of day only
time [ (p) ] with time zone	timetz	12 bytes	00:00:00+1359 - 24:00:00-1359	time of day only, with time zone
timestamp [ (p) ] [ without time zone ]		8 bytes	4713 BC - 294,277 AD	both date and time

**Table 6.1** Greenplum Database Built-in Data Types

Name <sup>1</sup>	Alias	Size	Range	Description
timestamp [ (p) ] with time zone	timestampz	8 bytes	4713 BC - 294,277 AD	both date and time, with time zone
xml		1 byte + <i>xml size</i>	xml of any length	variable unlimited length

1. For variable length data types (such as char, varchar, text, xml, etc.) if the data is greater than or equal to 127 bytes, the storage overhead is 4 bytes instead of 1.

# 7. Character Set Support

The character set support in Greenplum Database allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding). The default character set is selected while initializing your Greenplum Database array using `gpinit` system. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

**Table 7.1** Greenplum Database Character Sets<sup>1</sup>

Name	Description	Language	Server?	Bytes/Char	Aliases
BIG5	Big Five	Traditional Chinese	No	1-2	WIN950, Windows950
EUC_CN	Extended UNIX Code-CN	Simplified Chinese	Yes	1-3	
EUC_JP	Extended UNIX Code-JP	Japanese	Yes	1-3	
EUC_KR	Extended UNIX Code-KR	Korean	Yes	1-3	
EUC_TW	Extended UNIX Code-TW	Traditional Chinese, Taiwanese	Yes	1-3	
GB18030	National Standard	Chinese	No	1-2	
GBK	Extended National Standard	Simplified Chinese	No	1-2	WIN936, Windows936
ISO_8859_5	ISO 8859-5, ECMA 113	Latin/Cyrillic	Yes	1	
ISO_8859_6	ISO 8859-6, ECMA 114	Latin/Arabic	Yes	1	
ISO_8859_7	ISO 8859-7, ECMA 118	Latin/Greek	Yes	1	
ISO_8859_8	ISO 8859-8, ECMA 121	Latin/Hebrew	Yes	1	
JOHAB	JOHA	Korean (Hangul)	Yes	1-3	
KOI8	KOI8-R(U)	Cyrillic	Yes	1	KOI8R
LATIN1	ISO 8859-1, ECMA 94	Western European	Yes	1	ISO88591
LATIN2	ISO 8859-2, ECMA 94	Central European	Yes	1	ISO88592
LATIN3	ISO 8859-3, ECMA 94	South European	Yes	1	ISO88593
LATIN4	ISO 8859-4, ECMA 94	North European	Yes	1	ISO88594
LATIN5	ISO 8859-9, ECMA 128	Turkish	Yes	1	ISO88599
LATIN6	ISO 8859-10, ECMA 144	Nordic	Yes	1	ISO885910
LATIN7	ISO 8859-13	Baltic	Yes	1	ISO885913
LATIN8	ISO 8859-14	Celtic	Yes	1	ISO885914
LATIN9	ISO 8859-15	LATIN1 with Euro and accents	Yes	1	ISO885915

**Table 7.1** Greenplum Database Character Sets<sup>1</sup>

Name	Description	Language	Server?	Bytes/Char	Aliases
LATIN10	ISO 8859-16, ASRO SR 14111	Romanian	Yes	1	ISO885916
MULE_INTERNAL	Mule internal code	Multilingual Emacs	Yes	1-4	
SJIS	Shift JIS	Japanese	No	1-2	Mskanji, ShiftJIS, WIN932, Windows932
SQL_ASCII	unspecified <sup>2</sup>	any	No	1	
UHC	Unified Hangul Code	Korean	No	1-2	WIN949, Windows949
UTF8	Unicode, 8-bit	all	Yes	1-4	Unicode
WIN866	Windows CP866	Cyrillic	Yes	1	ALT
WIN874	Windows CP874	Thai	Yes	1	
WIN1250	Windows CP1250	Central European	Yes	1	
WIN1251	Windows CP1251	Cyrillic	Yes	1	WIN
WIN1252	Windows CP1252	Western European	Yes	1	
WIN1253	Windows CP1253	Greek	Yes	1	
WIN1254	Windows CP1254	Turkish	Yes	1	
WIN1255	Windows CP1255	Hebrew	Yes	1	
WIN1256	Windows CP1256	Arabic	Yes	1	
WIN1257	Windows CP1257	Baltic	Yes	1	
WIN1258	Windows CP1258	Vietnamese	Yes	1	ABC, TCVN, TCVN5712, VSCII

1. Not all APIs support all the listed character sets. For example, the JDBC driver does not support MULE\_INTERNAL, LATIN6, LATIN8, and LATIN10.
2. The SQL\_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL\_ASCII setting as a client encoding. SQL\_ASCII is not supported as a server encoding.

## Setting the Character Set

`gpinit` system defines the default character set for a Greenplum Database system by reading the setting of the `ENCODING` parameter in the `gp_init_config` file at initialization time. The default character set is `UNICODE` or `UTF8`.

You can create a database with a different character set besides what is used as the system-wide default. For example:

```
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

**Important:** Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The `LC_COLLATE` and `LC_CTYPE` settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by `gpinit` system, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to `C` or `POSIX` during initialization time, thus disabling any real locale awareness.

## Character Set Conversion Between Server and Client

Greenplum Database supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the master `pg_conversion` system catalog table. Greenplum Database comes with some predefined conversions or you can create a new conversion using the SQL command `CREATE CONVERSION`.

**Table 7.2** Client/Server Character Set Conversions

Server Character Set	Available Client Character Sets
BIG5	not supported as a server encoding
EUC_CN	EUC_CN, MULE_INTERNAL, UTF8
EUC_JP	EUC_JP, MULE_INTERNAL, SJIS, UTF8
EUC_KR	EUC_KR, MULE_INTERNAL, UTF8
EUC_TW	EUC_TW, BIG5, MULE_INTERNAL, UTF8
GB18030	not supported as a server encoding
GBK	not supported as a server encoding
ISO_8859_5	ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866, WIN1251
ISO_8859_6	ISO_8859_6, UTF8
ISO_8859_7	ISO_8859_7, UTF8
ISO_8859_8	ISO_8859_8, UTF8
JOHAB	JOHAB, UTF8
KOI8	KOI8, ISO_8859_5, MULE_INTERNAL, UTF8, WIN866, WIN1251
LATIN1	LATIN1, MULE_INTERNAL, UTF8
LATIN2	LATIN2, MULE_INTERNAL, UTF8, WIN1250
LATIN3	LATIN3, MULE_INTERNAL, UTF8
LATIN4	LATIN4, MULE_INTERNAL, UTF8
LATIN5	LATIN5, UTF8
LATIN6	LATIN6, UTF8
LATIN7	LATIN7, UTF8
LATIN8	LATIN8, UTF8
LATIN9	LATIN9, UTF8
LATIN10	LATIN10, UTF8

**Table 7.2** Client/Server Character Set Conversions

Server Character Set	Available Client Character Sets
MULE_INTERNAL	MULE_INTERNAL, BIG5, EUC_CN, EUC_JP, EUC_KR, EUC_TW, ISO_8859_5, KOI8, LATIN1 to LATIN4, SJIS, WIN866, WIN1250, WIN1251
SJIS	not supported as a server encoding
SQL_ASCII	not supported as a server encoding
UHC	not supported as a server encoding
UTF8	all supported encodings
WIN866	WIN866
ISO_8859_5	KOI8, MULE_INTERNAL, UTF8, WIN1251
WIN874	WIN874, UTF8
WIN1250	WIN1250, LATIN2, MULE_INTERNAL, UTF8
WIN1251	WIN1251, ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866
WIN1252	WIN1252, UTF8
WIN1253	WIN1253, UTF8
WIN1254	WIN1254, UTF8
WIN1255	WIN1255, UTF8
WIN1256	WIN1256, UTF8
WIN1257	WIN1257, UTF8
WIN1258	WIN1258, UTF8

To enable automatic character set conversion, you have to tell Greenplum Database the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.
- Using `SET client_encoding TO`. Setting the client encoding can be done with this SQL command:  

```
=> SET CLIENT_ENCODING TO 'value';
```

 To query the current client encoding:  

```
=> SHOW client_encoding;
```

 To return to the default encoding:  

```
=> RESET client_encoding;
```
- Using the `PGCLIENTENCODING` environment variable. When `PGCLIENTENCODING` is defined in the client's environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)

- Setting the configuration parameter `client_encoding`. If `client_encoding` is set in the master `postgresql.conf` file, that client encoding is automatically selected when a connection to Greenplum Database is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible — suppose you chose `EUC_JP` for the server and `LATIN1` for the client, then some Japanese characters do not have a representation in `LATIN1` — then an error is reported.

If the client character set is defined as `SQL_ASCII`, encoding conversion is disabled, regardless of the server's character set. The use of `SQL_ASCII` is unwise unless you are working with all-ASCII data. `SQL_ASCII` is not supported as a server encoding.

## 8. Server Configuration Parameters

There are many configuration parameters that affect the behavior of the Greenplum Database system. Many of these configuration parameters have the same names, settings, and behaviors as in a regular PostgreSQL database system. In this guide, the parameters are listed in alphabetic order. For a list of parameters organized by functionality, see “Configuration Parameter Categories” in Chapter 3 “Configuring Your Greenplum System” of the *Greenplum Database System Administration Guide*.

### Parameter Types and Values

All parameter names are case-insensitive. Every parameter takes a value of one of four types: Boolean, integer, floating point, or string. Boolean values may be written as ON, OFF, TRUE, FALSE, YES, NO, 1, 0 (all case-insensitive).

Some settings specify a memory size or time value. Each of these has an implicit unit, which is either kilobytes, blocks (typically eight kilobytes), milliseconds, seconds, or minutes. Valid memory size units are **kB** (kilobytes), **MB** (megabytes), and **GB** (gigabytes). Valid time units are **ms** (milliseconds), **s** (seconds), **min** (minutes), **h** (hours), and **d** (days). Note that the multiplier for memory units is 1024, not 1000. A valid time expression contains a number and a unit. When specifying a memory or time unit using the SET command, enclose the value in quotes. For example:

```
SET work_mem TO '200MB';
```

**Note:** There is no space between the value and the unit names.

### Setting Parameters

Many of the configuration parameters have limitations on who can change them and where or when they can be set. For example, to change certain parameters, you must be a Greenplum Database superuser. Other parameters require a restart of the system for the changes to take effect. A parameter that is classified as *session* can be set at the system level (in the `postgresql.conf` file), at the database-level (using `ALTER DATABASE`), at the role-level (using `ALTER ROLE`), or at the session-level (using `SET`). System parameters can only be set in the `postgresql.conf` file.

In Greenplum Database, the master and each segment instance has its own `postgresql.conf` file (located in their respective data directories). Some parameters are considered *local* parameters, meaning that each segment instance looks to its own `postgresql.conf` file to get the value of that parameter. You must set local parameters on every instance in the system (master and segments). Others parameters are considered *master* parameters. Master parameters need only be set at the master instance.

This table describes the Set Classification values in [Table 8.2, “Server Configuration Parameters”](#) on page 477 .

**Table 8.1** Settable Classifications

Set Classification	Description
master or local	<p>A <i>master</i> parameter only needs to be set in the <code>postgresql.conf</code> file of the Greenplum master instance. The value for this parameter is then either passed to (or ignored by) the segments at run time.</p> <p>A local parameter must be set in the <code>postgresql.conf</code> file of the master AND each segment instance. Each segment instance looks to its own configuration to get the value for the parameter. Local parameters always requires a system restart for changes to take effect.</p>
session or system	<p><i>Session</i> parameters can be changed on the fly within a database session, and can have a hierarchy of settings: at the system level (<code>postgresql.conf</code>), at the database level (<code>ALTER DATABASE . . . SET</code>), at the role level (<code>ALTER ROLE . . . SET</code>), or at the session level (<code>SET</code>). If the parameter is set at multiple levels, then the most granular setting takes precedence (for example, session overrides role, role overrides database, and database overrides system).</p> <p>A <i>system</i> parameter can only be changed via the <code>postgresql.conf</code> file(s).</p>
restart or reload	When changing parameter values in the <code>postgrsql.conf</code> file(s), some require a <i>restart</i> of Greenplum Database for the change to take effect. Other parameter values can be refreshed by just reloading the server configuration file (using <code>gpstop -u</code> ), and do not require stopping the system.
superuser	These session parameters can only be set by a database superuser. Regular database users cannot set this parameter.
read only	These parameters are not settable by database users or superusers. The current value of the parameter can be shown but not altered.

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
<code>add_missing_from</code>	Boolean	off	Automatically adds missing table references to FROM clauses. Present for compatibility with releases of PostgreSQL prior to 8.1, where this behavior was allowed by default.	master session reload
<code>application_name</code>	string		Sets the application name for a client session. For example, if connecting via <code>psql</code> , this will be set to <code>psql</code> . Setting an application name allows it to be reported in log messages and statistics views.	master session reload
<code>array_nulls</code>	Boolean	on	This controls whether the array input parser recognizes unquoted NULL as specifying a null array element. By default, this is on, allowing array values containing null values to be entered. Greenplum Database versions before 3.0 did not support null values in arrays, and therefore would treat NULL as specifying a normal array element with the string value 'NULL'.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
authentication_timeout	Any valid time expression (number and unit)	1min	Maximum time to complete client authentication. This prevents hung clients from occupying a connection indefinitely.	local system restart
backslash_quote	on (allow '\' always) off (reject always) safe_encoding (allow only if client encoding does not allow ASCII \ within a multibyte character)	safe_encoding	This controls whether a quote mark can be represented by \' in a string literal. The preferred, SQL-standard way to represent a quote mark is by doubling it (") but PostgreSQL has historically also accepted \'. However, use of \' creates security risks because in some client character set encodings, there are multibyte characters in which the last byte is numerically equivalent to ASCII \.	master session reload
block_size	number of bytes	32768	Reports the size of a disk block.	read only
bonjour_name	string	unset	Specifies the Bonjour broadcast name. By default, the computer name is used, specified as an empty string. This option is ignored if the server was not compiled with Bonjour support.	master system restart
check_function_bodies	Boolean	on	When set to off, disables validation of the function body string during CREATE FUNCTION. Disabling validation is occasionally useful to avoid problems such as forward references when restoring function definitions from a dump.	master session reload
client_encoding	character set	UTF8	Sets the client-side encoding (character set). The default is to use the same as the database encoding. See <a href="#">Supported Character Sets</a> in the PostgreSQL documentation.	master session reload
client_min_messages	DEBUG5 DEBUG4 DEBUG3 DEBUG2 DEBUG1 LOG NOTICE WARNING ERROR FATAL PANIC	NOTICE	Controls which message levels are sent to the client. Each level includes all the levels that follow it. The later the level, the fewer messages are sent.	master session reload
cpu_index_tuple_cost	floating point	0.005	Sets the planner's estimate of the cost of processing each index row during an index scan. This is measured as a fraction of the cost of a sequential page fetch.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
cpu_operator_cost	floating point	0.0025	Sets the planner's estimate of the cost of processing each operator in a WHERE clause. This is measured as a fraction of the cost of a sequential page fetch.	master session reload
cpu_tuple_cost	floating point	0.01	Sets the planner's estimate of the cost of processing each row during a query. This is measured as a fraction of the cost of a sequential page fetch.	master session reload
cursor_tuple_fraction	integer	1	Tells the query planner how many rows are expected to be fetched in a cursor query, thereby allowing the planner to use this information to optimize the query plan. The default of 1 means all rows will be fetched.	master session reload
custom_variable_classes	comma-separated list of class names	unset	Specifies one or several class names to be used for custom variables. A custom variable is a variable not normally known to the server but used by some add-on module. Such variables must have names consisting of a class name, a dot, and a variable name.	local system restart
DateStyle	<format>, <date style> where <format> is ISO, Postgres, SQL, or German and <date style> is DMY, MDY, or YMD.	ISO, MDY	Sets the display format for date and time values, as well as the rules for interpreting ambiguous date input values. This variable contains two independent components: the output format specification and the input/output specification for year/month/day ordering.	master session reload
db_user_namespace	Boolean	off	This enables per-database user names. If on, you should create users as <i>username@dbname</i> . To create ordinary global users, simply append @ when specifying the user name in the client.	local system restart
deadlock_timeout	Any valid time expression (number and unit)	1s	The time to wait on a lock before checking to see if there is a deadlock condition. On a heavily loaded server you might want to raise this value. Ideally the setting should exceed your typical transaction time, so as to improve the odds that a lock will be released before the waiter decides to check for deadlock.	local system restart
debug_assertions	Boolean	off	Turns on various assertion checks.	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
debug_pretty_print	Boolean	off	Indents debug output to produce a more readable but much longer output format. <i>client_min_messages</i> or <i>log_min_messages</i> must be DEBUG1 or lower.	master session reload
debug_print_parse	Boolean	off	For each executed query, prints the resulting parse tree. <i>client_min_messages</i> or <i>log_min_messages</i> must be DEBUG1 or lower.	master session reload
debug_print_plan	Boolean	off	For each executed query, prints the Greenplum parallel query execution plan. <i>client_min_messages</i> or <i>log_min_messages</i> must be DEBUG1 or lower.	master session reload
debug_print_prelim_plan	Boolean	off	For each executed query, prints the preliminary query plan. <i>client_min_messages</i> or <i>log_min_messages</i> must be DEBUG1 or lower.	master session reload
debug_print_rewritten	Boolean	off	For each executed query, prints the query rewriter output. <i>client_min_messages</i> or <i>log_min_messages</i> must be DEBUG1 or lower.	master session reload
debug_print_slice_table	Boolean	off	For each executed query, prints the Greenplum query slice plan. <i>client_min_messages</i> or <i>log_min_messages</i> must be DEBUG1 or lower.	master session reload
default_statistics_target	integer > 0	25	Sets the default statistics target for table columns that have not had a column-specific target set via ALTER TABLE SET STATISTICS. Larger values increase the time needed to do ANALYZE, but may improve the quality of the planner's estimates.	master session reload
default_tablespace	name of a tablespace	unset	The default tablespace in which to create objects (tables and indexes) when a CREATE command does not explicitly specify a tablespace.	master session reload
default_transaction_isolation	read committed read uncommitted repeatable read serializable	read committed	Controls the default isolation level of each new transaction.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
default_transaction_read_only	Boolean	off	Controls the default read-only status of each new transaction. A read-only SQL transaction cannot alter non-temporary tables.	master session reload
dynamic_library_path	a list of absolute directory paths separated by colons	\$libdir	If a dynamically loadable module needs to be opened and the file name specified in the CREATE FUNCTION or LOAD command does not have a directory component (i.e. the name does not contain a slash), the system will search this path for the required file. The compiled-in PostgreSQL package library directory is substituted for \$libdir. This is where the modules provided by the standard PostgreSQL distribution are installed.	local system restart
effective_cache_size	floating point	512MB	Sets the planner's assumption about the effective size of the disk cache that is available to a single query. This is factored into estimates of the cost of using an index; a higher value makes it more likely index scans will be used, a lower value makes it more likely sequential scans will be used. This parameter has no effect on the size of shared memory allocated by a Greenplum server instance, nor does it reserve kernel disk cache; it is used only for estimation purposes.	master session reload
enable_bitmapscan	Boolean	on	Enables or disables the query planner's use of bitmap-scan plan types. Note that this is different than a Bitmap Index Scan. A Bitmap Scan means that indexes will be dynamically converted to bitmaps in memory when appropriate, giving faster index performance on complex queries against very large tables. It is used when there are multiple predicates on different indexed columns. Each bitmap per column can be compared to create a final list of selected tuples.	master session reload
enable_groupagg	Boolean	on	Enables or disables the query planner's use of group aggregation plan types.	master session reload
enable_hashagg	Boolean	on	Enables or disables the query planner's use of hash aggregation plan types.	master session reload
enable_hashjoin	Boolean	on	Enables or disables the query planner's use of hash-join plan types.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
enable_indexscan	Boolean	on	Enables or disables the query planner's use of index-scan plan types.	master session reload
enable_mergejoin	Boolean	off	Enables or disables the query planner's use of merge-join plan types. Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the 'same place' in the sort order. In practice this means that the join operator must behave like equality.	master session reload
enable_nestloop	Boolean	off	Enables or disables the query planner's use of nested-loop join plans. It's not possible to suppress nested-loop joins entirely, but turning this variable off discourages the planner from using one if there are other methods available.	master session reload
enable_seqscan	Boolean	on	Enables or disables the query planner's use of sequential scan plan types. It's not possible to suppress sequential scans entirely, but turning this variable off discourages the planner from using one if there are other methods available.	master session reload
enable_sort	Boolean	on	Enables or disables the query planner's use of explicit sort steps. It's not possible to suppress explicit sorts entirely, but turning this variable off discourages the planner from using one if there are other methods available.	master session reload
enable_tidscan	Boolean	on	Enables or disables the query planner's use of tuple identifier (TID) scan plan types.	master session reload
escape_string_warning	Boolean	on	When on, a warning is issued if a backslash (\) appears in an ordinary string literal ('...' syntax). Escape string syntax (E'...') should be used for escapes, because in future versions, ordinary strings will have the SQL standard-conforming behavior of treating backslashes literally.	master session reload
explain_pretty_print	Boolean	on	Determines whether EXPLAIN VERBOSE uses the indented or non-indented format for displaying detailed query-tree dumps.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
extra_float_digits	integer	0	Adjusts the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits. The value can be set as high as 2, to include partially-significant digits; this is especially useful for dumping float data that needs to be restored exactly. Or it can be set negative to suppress unwanted digits.	master session reload
from_collapse_limit	1- <i>n</i>	20	The planner will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Smaller values reduce planning time but may yield inferior query plans.	master session reload
gp_adjust_selectivity_for_outerjoins	Boolean	on	Enables the selectivity of NULL tests over outer joins.	master session reload
gp_analyze_relative_error	floating point < 1.0	0.25	Sets the estimated acceptable error in the cardinality of the table — a value of 0.5 is supposed to be equivalent to an acceptable error of 50% (this is the default value used in PostgreSQL). If the statistics collected during ANALYZE are not producing good estimates of cardinality for a particular table attribute, decreasing the relative error fraction (accepting less error) tells the system to sample more rows.	master session reload
gp_appendonly_compaction	Boolean	on	Enables compacting segment files during VACUUM commands. When disabled, VACUUM only truncates the segment files to the EOF value, as is the current behavior. The administrator may want to disable compaction in high I/O load situations or low space situations.	master session reload
gp_appendonly_compaction_threshold	integer(%)	10	Sets the threshold ratio (as a percentage) of hidden tuples to allow compaction of the segment file. If the ratio of hidden tuples in a segment file on a segment is less than this threshold, the segment file is not compacted on a full VACUUM call, and a log message is issued.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_autostats_mode	none on_change on_no_stats	on_no_stats	<p>Specifies the mode for triggering automatic statistics collection with <code>ANALYZE</code>. The <code>on_no_stats</code> option triggers statistics collection for <code>CREATE TABLE AS SELECT</code>, <code>INSERT</code>, or <code>COPY</code> operations on any table that has no existing statistics.</p> <p>The <code>on_change</code> option triggers statistics collection only when the number of rows affected meets or exceeds the threshold defined by <code>gp_autostats_on_change_threshold</code>. Operations that can trigger automatic statistics collection with <code>on_change</code> are:</p> <pre>CREATE TABLE AS SELECT UPDATE DELETE INSERT COPY</pre> <p>Default is <code>on_no_stats</code>.</p>	master session reload
gp_autostats_on_change_threshold	integer	2147483647	Specifies the threshold for automatic statistics collection when <code>gp_autostats_mode</code> is set to <code>on_change</code> . When a triggering table operation affects a number of rows exceeding this threshold, <code>ANALYZE</code> is added and statistics are collected for the table.	master session reload
gp_backup_directIO	on, off	off	<p>Direct I/O allows Greenplum Database to bypass the buffering of memory within the file system cache. When Direct I/O is used for a file, data is transferred directly from the disk to the application buffer, without the use of the file buffer cache.</p> <p>Direct I/O is supported only on Red Hat Enterprise Linux, CentOS, and SUSE.</p>	local session reload
gp_backup_directIO_read_chunk_mb		20 MB	<p>Sets the chunk size in MB when Direct I/O is enabled with <code>gp_backup_directIO</code>. The default chunk size is 20MB.</p> <p>The default value is the optimal setting. Decreasing it will increase the backup time and increasing it will result in little change to backup time.</p>	local session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_cached_segworkers_threshold	integer > 0	5	When a user starts a session with Greenplum Database and issues a query, the system creates groups or 'gangs' of worker processes on each segment to do the work. After the work is done, the segment worker processes are destroyed except for a cached number which is set by this parameter. A lower setting conserves system resources on the segment hosts, but a higher setting may improve performance for power-users that want to issue many complex queries in a row.	master session reload
gp_command_count	integer > 0	1	Shows how many commands the master has received from the client. Note that a single SQLcommand might actually involve more than one command internally, so the counter may increment by more than one for a single query. This counter also is shared by all of the segment processes working on the command.	read only
gp_connectemc_mode	on, off, local, remote	on	Controls the ConnectEMC event logging and dial-home capabilities of Greenplum Command Center on the EMC Greenplum Data Computing Appliance (DCA). ConnectEMC must be installed in order to generate events. Allowed values are: <ul style="list-style-type: none"> <li>on (the default) - log events to the gpperfmon database and send dial-home notifications to EMC Support</li> <li>off - turns off ConnectEMC event logging and dial-home capabilities</li> <li>local - log events to the gpperfmon database only</li> <li>remote - sends dial-home notifications to EMC Support (does not log events to the gpperfmon database)</li> </ul>	master system restart superuser
gp_connections_per_thread	integer	64	A value larger than or equal to the number of primary segments means that each slice in a query plan will get its own thread when dispatching to the segments. A value of 0 indicates that the dispatcher should use a single thread when dispatching all query plan slices to a segment. Lower values will use more threads, which utilizes more resources on the master. Typically, the default does not need to be changed unless there is a known throughput performance problem.	master session reload
gp_content	integer		The local content id if a segment.	read only
gp_dbid	integer		The local content dbid if a segment.	read only

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_debug_linger	Any valid time expression (number and unit)	0	Number of seconds for a Greenplum process to linger after a fatal internal error.	master session reload
gp_dynamic_partition_pruning	on/off	on	Enables plans that can dynamically eliminate the scanning of partitions.	master session reload
gp_email_from	string		The email address used to send email alerts, in the format of: <code>'username@domain.com'</code> or <code>'Name &lt;username@domain.com&gt;'</code>	master system restart
gp_email_smtp_password	string		The password/passphrase used to authenticate with the SMTP server.	master system restart
gp_email_smtp_server	string		The fully qualified domain name or IP address and port of the SMTP server to use to send the email alerts. Must be in the format of: <code>smtp_servername.domain.com:port</code>	master system restart
gp_email_smtp_userid	string		The user id used to authenticate with the SMTP server.	master system restart
gp_email_to	string		A semi-colon (;) separated list of email addresses to receive email alert messages to in the format of: <code>'username@domain.com'</code> or <code>'Name &lt;username@domain.com&gt;'</code> If this parameter is not set, then email alerts are disabled.	master system restart
gp_enable_adaptive_nestloop	Boolean	on	Enables the query planner to use a new type of join node called “Adaptive Nestloop” at query execution time. This causes the planner to favor a hash-join over a nested-loop join if the number of rows on the outer side of the join exceeds a precalculated threshold. This parameter improves performance of index operations, which previously favored slower nested-loop joins.	master session reload
gp_enable_agg_distinct	Boolean	on	Enables or disables two-phase aggregation to compute a single distinct-qualified aggregate. This applies only to subqueries that include a single distinct-qualified aggregate function.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_enable_agg_distinct_pruning	Boolean	on	Enables or disables three-phase aggregation and join to compute distinct-qualified aggregates. This applies only to subqueries that include one or more distinct-qualified aggregate functions.	master session reload
gp_enable_direct_dispatch	Boolean	on	Enables or disables the dispatching of targeted query plans for queries that access data on a single segment. When on, queries that target rows on a single segment will only have their query plan dispatched to that segment (rather than to all segments). This significantly reduces the response time of qualifying queries as there is no interconnect setup involved. Direct dispatch does require more CPU utilization on the master.	master system restart
gp_enable_fallback_plan	Boolean	on	Allows use of disabled plan types when a query would not be feasible without them.	master session reload
gp_enable_fast_sri	Boolean	on	When set to on, the query planner plans single row inserts so that they are sent directly to the correct segment instance (no motion operation required). This significantly improves performance of single-row-insert statements.	master session reload
gp_enable_gpperfmon	Boolean	off	Enables or disables the data collection agents of Greenplum Command Center.	local system restart
gp_enable_groupect_distinct_gather	Boolean	on	Enables or disables gathering data to a single node to compute distinct-qualified aggregates on grouping extension queries. When this parameter and gp_enable_groupect_distinct_pruning are both enabled, the planner uses the cheaper plan.	master session reload
gp_enable_groupect_distinct_pruning	Boolean	on	Enables or disables three-phase aggregation and join to compute distinct-qualified aggregates on grouping extension queries. Usually, enabling this parameter generates a cheaper query plan that the planner will use in preference to existing plan.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
<code>gp_enable_multiphase_agg</code>	Boolean	on	Enables or disables the query planner's use of two or three-stage parallel aggregation plans. This approach applies to any subquery with aggregation. If <code>gp_enable_multiphase_agg</code> is off, then <code>gp_enable_agg_distinct</code> and <code>gp_enable_agg_distinct_pruning</code> are disabled.	master session reload
<code>gp_enable_predicate_propagation</code>	Boolean	on	When enabled, the query planner applies query predicates to both table expressions in cases where the tables are joined on their distribution key column(s). Filtering both tables prior to doing the join (when possible) is more efficient.	master session reload
<code>gp_enable_preunique</code>	Boolean	on	Enables two-phase duplicate removal for SELECT DISTINCT queries (not SELECT COUNT(DISTINCT)). When enabled, it adds an extra SORT DISTINCT set of plan nodes before motioning. In cases where the distinct operation greatly reduces the number of rows, this extra SORT DISTINCT is much cheaper than the cost of sending the rows across the Interconnect.	master session reload
<code>gp_enable_sequential_window_plans</code>	Boolean	on	If on, enables non-parallel (sequential) query plans for queries containing window function calls. If off, evaluates compatible window functions in parallel and rejoins the results. This is an experimental parameter.	master session reload
<code>gp_enable_sort_distinct</code>	Boolean	on	Enable duplicates to be removed while sorting.	master session reload
<code>gp_enable_sort_limit</code>	Boolean	on	Enable LIMIT operation to be performed while sorting. Sorts more efficiently when the plan requires the first <i>limit_number</i> of rows at most.	master session reload
<code>gp_external_enable_exec</code>	Boolean	on	Enables or disables the use of external tables that execute OS commands or scripts on the segment hosts ( <code>CREATE EXTERNAL TABLE EXECUTE</code> syntax). Must be enabled if using the Command Center or MapReduce features.	master system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_external_grant_privileges	Boolean	off	In releases prior to 4.0, enables or disables non-superusers to issue a <code>CREATE EXTERNAL [WEB] TABLE</code> command in cases where the <code>LOCATION</code> clause specifies <code>http</code> or <code>gpfdist</code> . In releases after 4.0, the ability to create an external table can be granted to a role using <code>CREATE ROLE</code> or <code>ALTER ROLE</code> .	master system restart
gp_external_max_segs	integer	64	Sets the number of segments that will scan external table data during an external table operation, the purpose being not to overload the system with scanning data and take away resources from other concurrent operations. This only applies to external tables that use the <code>gpfdist://</code> protocol to access external table data.	master system restart
gp_filerep_tcp_keepalives_count	number of lost keepalives	2	How many keepalives may be lost before the connection is considered dead. A value of 0 uses the system default. If <code>TCP_KEEPCNT</code> is not supported, this parameter must be 0.  Use this parameter for all connections that are between a primary and mirror segment. Use <code>tcp_keepalives_count</code> for settings that are not between a primary and mirror segment.	local system restart
gp_filerep_tcp_keepalives_idle	number of seconds	1 min	Number of seconds between sending keepalives on an otherwise idle connection. A value of 0 uses the system default. If <code>TCP_KEEPIDLE</code> is not supported, this parameter must be 0.  Use this parameter for all connections that are between a primary and mirror segment. Use <code>tcp_keepalives_idle</code> for settings that are not between a primary and mirror segment.	local system restart
gp_filerep_tcp_keepalives_interval	number of seconds	30 sec	How many seconds to wait for a response to a keepalive before retransmitting. A value of 0 uses the system default. If <code>TCP_KEEPINTVL</code> is not supported, this parameter must be 0.  Use this parameter for all connections that are between a primary and mirror segment. Use <code>tcp_keepalives_interval</code> for settings that are not between a primary and mirror segment.	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_fts_probe_interval	10 seconds or greater	1min	Specifies the polling interval for the fault detection process ( <i>ftsprobe</i> ). The <i>ftsprobe</i> process will take approximately this amount of time to detect a segment failure.	master system restart
gp_fts_probe_threadcount	1 - 128	16	Specifies the number of <i>ftsprobe</i> threads to create. This parameter should be set to a value equal to or greater than the number of segments per host.	master system restart
gp_fts_probe_timeout	10 seconds or greater	20 secs	Specifies the allowed timeout for the fault detection process ( <i>ftsprobe</i> ) to establish a connection to a segment before declaring it down.	master system restart
gp_gpperfmon_send_interval	Any valid time expression (number and unit)	1sec	Sets the frequency that the Greenplum Database server processes send query execution updates to the data collection agent processes used by Command Center. Query operations (iterators) executed during this interval are sent through UDP to the segment monitor agents. If you find that an excessive number of UDP packets are dropped during long-running, complex queries, you may consider increasing this value.	master system restart
gp_hadoop_home	Valid directory name	Value of HADOOP_HOME	The Hadoop home directory. This parameter has the same value as the required environmental variable HADOOP_HOME.	local session reload
gp_hadoop_target_version	gphd-1.0 gphd-1.1 gphd-1.2 gphd-2.0 gpmr-1.0 gpmr-1.2 cdh3u2 cdh4.1	gphd-1.1	The installed version of Greenplum Hadoop target.	local session reload
gp_hashjoin_tuples_per_bucket	integer	5	Sets the target density of the hash table used by HashJoin operations. A smaller value will tend to produce larger hash tables, which can increase join performance.	master session reload
gp_idf_deduplicate	integer		Changes the strategy to compute and process MEDIAN, and PERCENTILE_DISC.	auto none force

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_interconnect_fc_method	CAPACITY LOSS	LOSS	Specifies the flow control method used for UDP interconnect when the value of <a href="#">gp_interconnect_type</a> is UDPIFC. For capacity based flow control, senders do not send packets when receivers do not have the capacity. Loss based flow control is based on capacity based flow control, and also tunes the sending speed according to packet losses.	master session reload
gp_interconnect_hash_multiplier	2-25	2	Sets the size of the hash table used by the UDP interconnect to track connections. This number is multiplied by the number of segments to determine the number of buckets in the hash table. Increasing the value may increase interconnect performance for complex multi-slice queries (while consuming slightly more memory on the segment hosts).	master session reload
gp_interconnect_queue_depth	1-2048	4	Sets the amount of data per-peer to be queued by the UDP interconnect on receivers (when data is received but no space is available to receive it the data will be dropped, and the transmitter will need to resend it). Increasing the depth from its default value will cause the system to use more memory; but may increase performance. It is reasonable for this to be set between 1 and 10. Queries with data skew potentially perform better when this is increased. Increasing this may radically increase the amount of memory used by the system.	master session reload
gp_interconnect_setup_timeout	Any valid time expression (number and unit)	2 hours	Time to wait for the Interconnect to complete setup before it times out. This parameter is used only when <a href="#">gp_interconnect_type</a> is set to UDP.	master session reload
gp_interconnect_snd_queue_depth	1 - 4096	2	Sets the amount of data per-peer to be queued by the UDP interconnect on senders. Increasing the depth from its default value will cause the system to use more memory; but may increase performance. Reasonable values for this parameter are between 1 and 4. Increasing the value might radically increase the amount of memory used by the system. This parameter is used only when <a href="#">gp_interconnect_type</a> is set to UDPIFC.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_interconnect_type	TCP UDP UDPIFC	UDPIFC	Sets the networking protocol used for Interconnect traffic. With the TCP protocol, Greenplum Database has an upper limit of 1000 segment instances - less than that if the query workload involves complex, multi-slice queries. UDP allows for greater interconnect scalability. Note that the Greenplum software does the additional packet verification and checking not performed by UDP, so reliability and performance is equivalent to TCP. UDPIFC specifies using UDP with flow control for interconnect traffic. Specify the interconnect flow control method with <a href="#">gp_interconnect_fc_method</a> .	local system restart
gp_log_format	csv text	csv	Specifies the format of the server log files. If using <i>gp_toolkit</i> administrative schema, the log files must be in csv format.	local system restart
gp_max_csv_line_length	number of bytes	1048576	The maximum length of a line in a CSV formatted file that will be imported into the system. The default is 1MB (1048576 bytes). Maximum allowed is 4MB (4194184 bytes). The default may need to be increased if using the <i>gp_toolkit</i> administrative schema to read Greenplum Database log files.	local system restart
gp_max_databases	integer	16	The maximum number of databases allowed in a Greenplum Database system.	master system restart
gp_max_filespaces	integer	8	The maximum number of tablespaces allowed in a Greenplum Database system.	master system restart
gp_max_local_distributed_cache	integer	1024	Sets the number of local to distributed transactions to cache. Higher settings may improve performance.	local system restart
gp_max_packet_size	512-65536	8192	Sets the size (in bytes) of messages sent by the UDP interconnect, and sets the tuple-serialization chunk size for both the UDP and TCP interconnect.	master system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_max_plan_size	integer	0	Specifies the total maximum uncompressed size of a query execution plan multiplied by the number of Motion operators (slices) in the plan. If the size of the query plan exceeds the value, the query is cancelled and an error is returned. A value of 0 means that the size of the plan is not monitored.  You can specify a value in KB,MB, or GB. The default unit is KB. For example, a value of 200 is 200KB. A value of 1GB is the same as 1024MB or 1048576KB.	master superuser session
gp_max_tablespace	integer	16	The maximum number of tablespaces allowed in a Greenplum Database system.	master system restart
gp_motion_cost_per_row	floating point	0	Sets the query planner cost estimate for a Motion operator to transfer a row from one segment to another, measured as a fraction of the cost of a sequential page fetch. If 0, then the value used is two times the value of <i>cpu_tuple_cost</i> .	master session reload
gp_num_contents_in_cluster	-	-	The number of primary segments in the Greenplum Database system.	read only
gp_reject_percent_threshold	1- <i>n</i>	300	For single row error handling on COPY and external table SELECTs, sets the number of rows processed before SEGMENT REJECT LIMIT <i>n</i> PERCENT starts calculating.	master session reload
gp_reraise_signal	Boolean	on	If enabled, will attempt to dump core if a fatal server error occurs.	master session reload
gp_resqueue_memory_policy	none, auto, eager_free	eager_free	Enables Greenplum memory management features.  In Greenplum Database 4.2 and later, the distribution algorithm <i>eager_free</i> , takes advantage of the fact that not all operators execute at the same time. The query plan is divided into stages and Greenplum Database eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.  When set to <i>none</i> , memory management is the same as in Greenplum Database releases prior to 4.1. When set to <i>auto</i> , query memory usage is controlled by <a href="#">statement_mem</a> and resource queue memory limits.	local system restart/reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_resqueue_priority	Boolean	on	Enables or disables query prioritization. When this parameter is disabled, existing priority settings are not evaluated at query run time.	local system restart
gp_resqueue_priority_cpucore_per_segment	0.1 - 512.0	segments = 4 master = 24	Specifies the number of CPU units per segment. In a configuration where one segment is configured per CPU core on a host, this unit is 1.0 (default). If an 8-core host is configured with four segments, the value would be 2.0. A master host typically only has one segment running on it (the master instance), so the value for the master should reflect the usage of all available CPU cores. Incorrect settings can result in CPU under-utilization. The default values are appropriate for the Greenplum Data Computing Appliance.	local system restart
gp_resqueue_priority_sweeper_interval	500 - 15000 ms	1000	Specifies the interval at which the sweeper process evaluates current CPU usage. When a new statement becomes active, its priority is evaluated and its CPU share determined when the next interval is reached.	local system restart
gp_role	dispatch execute utility		The role of this server process — set to <i>dispatch</i> for the master and <i>execute</i> for a segment.	read only
gp_safefswritesize	integer	0	Specifies a minimum size for safe write operations to append-optimized tables in a non-mature file system. When a number of bytes greater than zero is specified, the append-optimized writer adds padding data up to that number in order to prevent data corruption due to file system errors. Each non-mature file system has a known safe write size that must be specified here when using Greenplum Database with that type of file system. This is commonly set to a multiple of the extent size of the file system; for example, Linux ext3 is 4096 bytes, so a value of 32768 is commonly used.	local system restart
gp_segment_connect_timeout	Any valid time expression (number and unit)	10min	Time that the Greenplum interconnect will try to connect to a segment instance over the network before timing out. Controls the network connection timeout between master and primary segments, and primary to mirror segment replication processes.	local system reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_segments_for_planner	0- <i>n</i>	0	Sets the number of primary segment instances for the planner to assume in its cost and size estimates. If 0, then the value used is the actual number of primary segments. This variable affects the planner's estimates of the number of rows handled by each sending and receiving process in Motion operators.	master session reload
gp_session_id	1- <i>n</i>	14	A system assigned ID number for a client session. Starts counting from 1 when the master instance is first started.	read only
gp_set_proc_affinity	Boolean	off	If enabled, when a Greenplum server process (postmaster) is started it will bind to a CPU.	master system restart
gp_set_read_only	Boolean	off	Set to on to disable writes to the database. Any in progress transactions must finish before read-only mode takes affect.	master session reload
gp_snmp_community	SNMP community name	public	Set to the community name you specified for your environment.	master system reload
gp_snmp_monitor_address	hostname:port		The <i>hostname:port</i> of your network monitor application. Typically, the port number is 162. If there are multiple monitor addresses, separate them with a comma.	master system reload
gp_snmp_use_inform_or_trap	inform trap	trap	Trap notifications are SNMP messages sent from one application to another (for example, between Greenplum Database and a network monitoring application). These messages are unacknowledged by the monitoring application, but generate less network overhead.  Inform notifications are the same as trap messages, except that the application sends an acknowledgement to the application that generated the alert.	master system reload
gp_statistics_pullup_from_child_partition	Boolean	on	Enables the query planner to utilize statistics from child tables when planning queries on the parent table.	master session reload
gp_statistics_use_fkeys	Boolean	off	When enabled, allows the optimizer to use foreign key information stored in the system catalog to optimize joins between foreign keys and primary keys.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_vmem_idle_resource_timeout	Any valid time expression (number and unit)	18s	If a database session is idle for longer than the time specified, the session will free system resources (such as shared memory), but remain connected to the database. This allows more concurrent connections to the database at one time.	master system restart
gp_vmem_protect_limit	integer	8192	<p>Sets the amount of memory (in number of MBs) that all postgres processes of an active segment instance can consume. To prevent over allocation of memory, set to:</p> $(X * \text{physical\_memory}) / \text{primary\_segments}$ <p>Where <i>X</i> is a value between 1.0 and 1.5. <i>X</i>=1 offers the best system performance. <i>X</i>=1.5 may cause more swapping on the system, but less queries will be cancelled.</p> <p>For example, on a segment host with 16GB physical memory and 4 primary segment instances the calculation would be:</p> $(1 * 16) / 4 = 4\text{GB}$ $4 * 1024 = 4096\text{MB}$ <p>If a query causes this limit to be exceeded, memory will not be allocated and the query will fail. Note that this is a local parameter and must be set for every segment in the system (primary and mirrors).</p>	local system restart
gp_vmem_protect_segworker_cache_limit	number of megabytes	500	If a query executor process consumes more than this configured amount, then the process will not be cached for use in subsequent queries after the process completes. Systems with lots of connections or idle processes may want to reduce this number to free more memory on the segments. Note that this is a local parameter and must be set for every segment.	local system restart
gp_workfile_checksumming	Boolean	on	Adds a checksum value to each block of a work file (or spill file) used by HashAgg and HashJoin query operators. This adds an additional safeguard from faulty OS disk drivers writing corrupted blocks to disk. When a checksum operation fails, the query will cancel and rollback rather than potentially writing bad data to disk.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
gp_workfile_compress_algorithm	none zlib	none	When a hash aggregation or hash join operation spills to disk during query processing, specifies the compression algorithm to use on the spill files. If using zlib, it must be in your \$PATH on all segments.	master session reload
gp_workfile_limit_per_query	kilobytes	0	Sets the maximum disk size an individual query is allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.	master session reload
gp_workfile_limit_per_segment	kilobytes	0	Sets the maximum total disk size that all running queries are allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.	local system restart
gpperfmon_port	integer	8888	Sets the port on which all data collection agents (for Command Center) communicate with the master.	master system restart
integer_datetimes	Boolean	on	Reports whether PostgreSQL was built with support for 64-bit-integer dates and times.	read only
IntervalStyle	postgres postgres_verbose sql_standard iso_8601	postgres	Sets the display format for interval values. The value <i>sql_standard</i> produces output matching SQL standard interval literals. The value <i>postgres</i> produces output matching PostgreSQL releases prior to 8.4 when the <a href="#">DateStyle</a> parameter was set to ISO. The value <i>postgres_verbose</i> produces output matching Greenplum releases prior to 3.3 when the <a href="#">DateStyle</a> parameter was set to non-ISO output. The value <i>iso_8601</i> will produce output matching the time interval <i>format with designators</i> defined in section 4.4.3.2 of ISO 8601. See the <a href="#">PostgreSQL 8.4 documentation</a> for more information.	master session reload
join_collapse_limit	1- <i>n</i>	20	The planner will rewrite explicit inner JOIN constructs into lists of FROM items whenever a list of no more than this many items in total would result. By default, this variable is set the same as <i>from_collapse_limit</i> , which is appropriate for most uses. Setting it to 1 prevents any reordering of inner JOINS. Setting this variable to a value between 1 and <i>from_collapse_limit</i> might be useful to trade off planning time against the quality of the chosen plan (higher values produce better plans).	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
keep_wal_segments	integer	5	For Greenplum Database master mirroring, sets the maximum number of processed WAL segment files that are saved by the by the active Greenplum Database master if a checkpoint operation occurs.  The segment files are used to synchronize the active master on the standby master.	master system reload superuser
krb_caseins_users	Boolean	off	Sets whether Kerberos user names should be treated case-insensitively. The default is case sensitive (off).	master system restart
krb_server_keyfile	path and file name	unset	Sets the location of the Kerberos server key file.	master system restart
krb_srvname	service name	postgres	Sets the Kerberos service name.	master system restart
lc_collate	<system dependent>		Reports the locale in which sorting of textual data is done. The value is determined when the Greenplum Database array is initialized.	read only
lc_ctype	<system dependent>		Reports the locale that determines character classifications. The value is determined when the Greenplum Database array is initialized.	read only
lc_messages	<system dependent>		Sets the language in which messages are displayed. The locales available depends on what was installed with your operating system - use <i>locale -a</i> to list available locales. The default value is inherited from the execution environment of the server. On some systems, this locale category does not exist. Setting this variable will still work, but there will be no effect. Also, there is a chance that no translated messages for the desired language exist. In that case you will continue to see the English messages.	local system restart
lc_monetary	<system dependent>		Sets the locale to use for formatting monetary amounts, for example with the <i>to_char</i> family of functions. The locales available depends on what was installed with your operating system - use <i>locale -a</i> to list available locales. The default value is inherited from the execution environment of the server.	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
lc_numeric	<system dependent>		Sets the locale to use for formatting numbers, for example with the <i>to_char</i> family of functions. The locales available depends on what was installed with your operating system - use <i>locale -a</i> to list available locales. The default value is inherited from the execution environment of the server.	local system restart
lc_time	<system dependent>		This parameter currently does nothing, but may in the future.	local system restart
listen_addresses	localhost, host names, IP addresses, * (all available IP interfaces)	*	Specifies the TCP/IP address(es) on which the server is to listen for connections from client applications - a comma-separated list of host names and/or numeric IP addresses. The special entry * corresponds to all available IP interfaces. If the list is empty, only UNIX-domain sockets can connect.	master system restart
local_preload_libraries			Comma separated list of shared library files to preload at the start of a client session.	local system restart
log_autostats	Boolean	off	Logs information about automatic <i>ANALYZE</i> operations related to <a href="#">gp_autostats_mode</a> and <a href="#">gp_autostats_on_change_threshold</a> .	master session reload superuser
log_connections	Boolean	off	This outputs a line to the server log detailing each successful connection. Some client programs, like <i>psql</i> , attempt to connect twice while determining if a password is required, so duplicate "connection received" messages do not always indicate a problem.	local system restart
log_disconnections	Boolean	off	This outputs a line in the server log at termination of a client session, and includes the duration of the session.	local system restart
log_dispatch_stats	Boolean	off	When set to "on," this parameter adds a log message with verbose information about the dispatch of the statement.	local system restart
log_duration	Boolean	off	Causes the duration of every completed statement which satisfies <i>log_statement</i> to be logged.	master session reload superuser

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
log_error_verbosity	TERSE DEFAULT VERBOSE	DEFAULT	Controls the amount of detail written in the server log for each message that is logged.	master session reload superuser
log_executor_stats	Boolean	off	For each query, write performance statistics of the query executor to the server log. This is a crude profiling instrument. Cannot be enabled together with <i>log_statement_stats</i> .	local system restart
log_hostname	Boolean	off	By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the host name as well. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.	local system restart
log_min_duration_statement	number of milliseconds, 0, -1	-1	Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 disables the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.	master session reload superuser
log_min_error_statement	DEBUG5 DEBUG4 DEBUG3 DEBUG2, DEBUG1 INFO NOTICE WARNING ERROR FATAL PANIC	ERROR	Controls whether or not the SQL statement that causes an error condition will also be recorded in the server log. All SQL statements that cause an error of the specified level or higher are logged. The default is PANIC (effectively turning this feature off for normal use). Enabling this option can be helpful in tracking down the source of any errors that appear in the server log.	master session reload superuser
log_min_messages	DEBUG5 DEBUG4 DEBUG3 DEBUG2 DEBUG1 INFO NOTICE WARNING ERROR LOG FATAL PANIC	WARNING	Controls which message levels are written to the server log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.	master session reload superuser

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
log_parser_stats	Boolean	off	For each query, write performance statistics of the query parser to the server log. This is a crude profiling instrument. Cannot be enabled together with <i>log_statement_stats</i> .	master session reload superuser
log_planner_stats	Boolean	off	For each query, write performance statistics of the query planner to the server log. This is a crude profiling instrument. Cannot be enabled together with <i>log_statement_stats</i> .	master session reload superuser
log_rotation_age	Any valid time expression (number and unit)	1d	Determines the maximum lifetime of an individual log file. After this time has elapsed, a new log file will be created. Set to zero to disable time-based creation of new log files.	local system restart
log_rotation_size	number of kilobytes	0	Determines the maximum size of an individual log file. After this many kilobytes have been emitted into a log file, a new log file will be created. Set to zero to disable size-based creation of new log files.	local system restart
log_statement	NONE DDL MOD ALL	ALL	Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.	master session reload superuser
log_statement_stats	Boolean	off	For each query, write total performance statistics of the query parser, planner, and executor to the server log. This is a crude profiling instrument.	master session reload superuser
log_timezone	string	unknown	Sets the time zone used for timestamps written in the log. Unlike <a href="#">TimeZone</a> , this value is system-wide, so that all sessions will report timestamps consistently. The default is <i>unknown</i> , which means to use whatever the system environment specifies as the time zone.	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
log_truncate_on_rotation	Boolean	off	Truncates (overwrites), rather than appends to, any existing log file of the same name. Truncation will occur only when a new file is being opened due to time-based rotation. For example, using this setting in combination with a log_filename such as gpseg#-%H.log would result in generating twenty-four hourly log files and then cyclically overwriting them. When off, pre-existing files will be appended to in all cases.	local system restart
max_appendonly_tables	2048	10000	Sets the maximum number of append-optimized relations that can be written to or loaded concurrently. Append-optimized table partitions and subpartitions are considered as unique tables against this limit. Increasing the limit will allocate more shared memory at server start.	master system restart
max_connections	10- <i>n</i>	250 on master 750 on segments	The maximum number of concurrent connections to the database server. In a Greenplum Database system, user client connections go through the Greenplum master instance only. Segment instances should allow 5-10 times the amount as the master. When you increase this parameter, <a href="#">max_prepared_transactions</a> must be increased as well. For more information about limiting concurrent connections, see the <i>Greenplum Database Database Administrator Guide</i> . Increasing this parameter may cause Greenplum Database to request more shared memory.	local system restart
max_files_per_process	integer	1000	Sets the maximum number of simultaneously open files allowed to each server subprocess. If the kernel is enforcing a safe per-process limit, you don't need to worry about this setting. Some platforms such as BSD, the kernel will allow individual processes to open many more files than the system can really support.	local system restart
max_fsm_pages	integer > 16 * <i>max_fsm_relations</i>	200000	Sets the maximum number of disk pages for which free space will be tracked in the shared free-space map. Six bytes of shared memory are consumed for each page slot.	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
max_fsm_relations	integer	1000	Sets the maximum number of relations for which free space will be tracked in the shared memory free-space map. Should be set to a value larger than the total number of: tables + indexes + system tables. It costs about 60 bytes of memory for each relation per segment instance. It is better to allow some room for overhead and set too high rather than too low.	local system restart
max_function_args	integer	100	Reports the maximum number of function arguments.	read only
max_identifier_length	integer	63	Reports the maximum identifier length.	read only
max_index_keys	integer	32	Reports the maximum number of index keys.	read only
max_locks_per_transaction	integer	128	The shared lock table is created with room to describe locks on <i>max_locks_per_transaction * (max_connections + max_prepared_transactions)</i> objects, so no more than this many distinct objects can be locked at any one time. This is not a hard limit on the number of locks taken by any one transaction, but rather a maximum average value. You might need to raise this value if you have clients that touch many different tables in a single transaction.	local system restart
max_prepared_transactions	integer	250 on master 250 on segments	Sets the maximum number of transactions that can be in the prepared state simultaneously. Greenplum uses prepared transactions internally to ensure data integrity across the segments. This value must be at least as large as the value of <a href="#">max_connections</a> on the master. Segment instances should be set to the same value as the master.	local system restart
max_resource_portals_per_transaction	integer	64	Sets the maximum number of simultaneously open user-declared cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue. Used for workload management.	master system restart
max_resource_queues	integer	9	Sets the maximum number of resource queues that can be created in a Greenplum Database system. Note that resource queues are system-wide (as are roles) so they apply to all databases in the system.	master system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
max_stack_depth	number of kilobytes	2MB	Specifies the maximum safe depth of the server's execution stack. The ideal setting for this parameter is the actual stack size limit enforced by the kernel (as set by <i>ulimit -s</i> or local equivalent), less a safety margin of a megabyte or so. Setting the parameter higher than the actual kernel limit will mean that a runaway recursive function can crash an individual backend process.	local system restart
max_statement_mem	number of kilobytes	2000MB	Sets the maximum memory limit for a query. Helps avoid out-of-memory errors on a segment host during query processing as a result of setting <i>statement_mem</i> too high. When <i>gp_resqueue_memory_policy=auto</i> , <i>statement_mem</i> and resource queue memory limits control query memory usage. Taking into account the configuration of a single segment host, calculate this setting as follows:  $\frac{(\text{segghost\_physical\_memory})}{(\text{average\_number\_concurrent\_queries})}$	master session reload superuser
password_encryption	Boolean	on	When a password is specified in CREATE USER or ALTER USER without writing either ENCRYPTED or UNENCRYPTED, this option determines whether the password is to be encrypted.	master session reload
pgstat_track_activity_query_size	integer	1024	Sets the maximum length limit for the query text stored in <i>current_query</i> column of the system catalog view <i>pg_stat_activity</i> . The minimum length is 1024 characters.	local system restart
pljava_classpath	string		A colon (:) separated list of the jar files containing the Java classes used in any PL/Java functions. The jar files listed here must also be installed on all Greenplum hosts in the following location: <i>\$GPHOME/lib/postgresql/java/</i>	master session reload
pljava_statement_cache_size	number of kilobytes	10	Sets the size in KB of the JRE MRU (Most Recently Used) cache for prepared statements.	master system restart superuser
pljava_release_lingering_savepoints	Boolean	true	If true, lingering savepoints used in PL/Java functions will be released on function exit. If false, savepoints will be rolled back.	master system restart superuser

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
pljava_vmoptions	string	-Xmx64M	Defines the startup options for the Java VM.	master system restart superuser
port	any valid port number	5432	The database listener port for a Greenplum instance. The master and each segment has its own port. Port numbers for the Greenplum system must also be changed in the <code>gp_segment_configuration</code> catalog. You must shut down your Greenplum Database system before changing port numbers.	local system restart
random_page_cost	floating point	100	Sets the planner's estimate of the cost of a nonsequentially fetched disk page. This is measured as a multiple of the cost of a sequential page fetch. A higher value makes it more likely a sequential scan will be used, a lower value makes it more likely an index scan will be used.	master session reload
repl_catchup_within_range	0 - 64	1	For Greenplum Database master mirroring, controls updates to the active master. If the number of WAL segment files that have not been processed by the <code>walsender</code> exceeds this value, Greenplum Database updates the active master.  If the number of segment files does not exceed the value, Greenplum Database blocks updates to the to allow the <code>walsender</code> process the files. If all WAL segments have been processed, the active master is updated.	master system reload superuser
replication_timeout	0 - INT_MAX	60000 ms (60 seconds)	For Greenplum Database master mirroring, sets the maximum time in milliseconds that the <code>walsender</code> process on the active master waits for a status message from the <code>walreceiver</code> process on the standby master. If a message is not received, the <code>walsender</code> logs an error message.  The <code>wal_receiver_status_interval</code> controls the interval between <code>walreceiver</code> status messages.	master system reload superuser
regex_flavor	advanced extended basic	advanced	The 'extended' setting may be useful for exact backwards compatibility with pre-7.4 releases of PostgreSQL.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
resource_cleanup_gangs_on_wait	Boolean	on	If a statement is submitted through a resource queue, clean up any idle query executor worker processes before taking a lock on the resource queue.	master system restart
resource_select_only	Boolean	off	Sets the types of queries managed by resource queues. If set to on, then SELECT, SELECT INTO, CREATE TABLE AS SELECT, and DECLARE CURSOR commands are evaluated. If set to off INSERT, UPDATE, and DELETE commands will be evaluated as well.	master system restart
search_path	a comma-separated list of schema names	\$user,public	Specifies the order in which schemas are searched when an object is referenced by a simple name with no schema component. When there are objects of identical names in different schemas, the one found first in the search path is used. The system catalog schema, <i>pg_catalog</i> , is always searched, whether it is mentioned in the path or not. When objects are created without specifying a particular target schema, they will be placed in the first schema listed in the search path. The current effective value of the search path can be examined via the SQL function <i>current_schemas()</i> . <i>current_schemas()</i> shows how the requests appearing in <i>search_path</i> were resolved.	master session reload
seq_page_cost	floating point	1	Sets the planner's estimate of the cost of a disk page fetch that is part of a series of sequential fetches.	master session reload
server_encoding	<system dependent>	UTF8	Reports the database encoding (character set). It is determined when the Greenplum Database array is initialized. Ordinarily, clients need only be concerned with the value of <i>client_encoding</i> .	read only
server_version	string	8.2.15	Reports the version of PostgreSQL that this release of Greenplum Database is based on.	read only
server_version_num	integer	80215	Reports the version of PostgreSQL that this release of Greenplum Database is based on as an integer.	read only
shared_buffers	integer > 16K * <i>max_connections</i>	125MB	Sets the amount of memory a Greenplum server instance uses for shared memory buffers. This setting must be at least 128 kilobytes and at least 16 kilobytes times <i>max_connections</i> .	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
shared_preload_libraries			A comma-separated list of shared libraries that are to be preloaded at server start. PostgreSQL procedural language libraries can be preloaded in this way, typically by using the syntax '\$libdir/plXXX' where XXX is pgsql, perl, tcl, or python. By preloading a shared library, the library startup time is avoided when the library is first used. If a specified library is not found, the server will fail to start.	local system restart
ssl	Boolean	off	Enables SSL connections.	master system restart
ssl_ciphers	string	ALL	Specifies a list of SSL ciphers that are allowed to be used on secure connections. See the openssl manual page for a list of supported ciphers.	master system restart
standard_conforming_strings	Boolean	off	Reports whether ordinary string literals ('...') treat backslashes literally, as specified in the SQL standard. The value is currently always off, indicating that backslashes are treated as escapes. It is planned that this will change to on in a future release when string literal syntax changes to meet the standard. Applications may check this parameter to determine how string literals will be processed. The presence of this parameter can also be taken as an indication that the escape string syntax (E'...') is supported.	read only
statement_mem	number of kilobytes	128MB	Allocates segment instance memory per query. The amount of memory allocated with this parameter cannot exceed <a href="#">max_statement_mem</a> or the memory limit on the resource queue through which the query was submitted. When <a href="#">gp_resqueue_memory_policy=auto</a> , statement_mem and resource queue memory limits control query memory usage.	master session reload
statement_timeout	number of milliseconds	0	Abort any statement that takes over the specified number of milliseconds. 0 turns off the limitation.	master session reload
stats_queue_level	Boolean	off	Collects resource queue statistics on database activity.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
superuser_reserved_connections	integer < <i>max_connections</i>	3	Determines the number of connection slots that are reserved for Greenplum Database superusers.	local system restart
tcp_keepalives_count	number of lost keepalives	0	How many keepalives may be lost before the connection is considered dead. A value of 0 uses the system default. If TCP_KEEPCNT is not supported, this parameter must be 0.  Use this parameter for all connections that are not between a primary and mirror segment. Use <code>gp_filerp_tcp_keepalives_count</code> for settings that are between a primary and mirror segment.	local system restart
tcp_keepalives_idle	number of seconds	0	Number of seconds between sending keepalives on an otherwise idle connection. A value of 0 uses the system default. If TCP_KEEPIDLE is not supported, this parameter must be 0.  Use this parameter for all connections that are not between a primary and mirror segment. Use <code>gp_filerp_tcp_keepalives_idle</code> for settings that are between a primary and mirror segment.	local system restart
tcp_keepalives_interval	number of seconds	0	How many seconds to wait for a response to a keepalive before retransmitting. A value of 0 uses the system default. If TCP_KEEPINTVL is not supported, this parameter must be 0.  Use this parameter for all connections that are not between a primary and mirror segment. Use <code>gp_filerp_tcp_keepalives_interval</code> for settings that are between a primary and mirror segment.	local system restart
temp_buffers	integer	1024	Sets the maximum number of temporary buffers used by each database session. These are session-local buffers used only for access to temporary tables. The setting can be changed within individual sessions, but only up until the first use of temporary tables within a session. The cost of setting a large value in sessions that do not actually need a lot of temporary buffers is only a buffer descriptor, or about 64 bytes, per increment. However if a buffer is actually used, an additional 8192 bytes will be consumed.	master session reload

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
TimeZone	time zone abbreviation		Sets the time zone for displaying and interpreting time stamps. The default is to use whatever the system environment specifies as the time zone. See <a href="#">Date/Time Keywords</a> in the PostgreSQL documentation.	local restart
timezone_abbreviations	string	Default	Sets the collection of time zone abbreviations that will be accepted by the server for date time input. The default is <code>Default</code> , which is a collection that works in most of the world. <code>Australia</code> and <code>India</code> , and other collections can be defined for a particular installation. Possible values are names of configuration files stored in <code>/share/postgresql/timezonesets/</code> in the installation directory.	master session reload
track_activities	Boolean	on	Enables the collection of statistics on the currently executing command of each session, along with the time at which that command began execution. When enabled, this information is not visible to all users, only to superusers and the user owning the session. This data can be accessed via the <code>pg_stat_activity</code> system view.	master session reload
track_counts	Boolean	off	Enables the collection of row and block level statistics on database activity. If enabled, the data that is produced can be accessed via the <code>pg_stat</code> and <code>pg_statio</code> family of system views.	local system restart
transaction_isolation	read committed serializable	read committed	Sets the current transaction's isolation level.	master session reload
transaction_read_only	Boolean	off	Sets the current transaction's read-only status.	master session reload
transform_null_equals	Boolean	off	When on, expressions of the form <code>expr = NULL</code> (or <code>NULL = expr</code> ) are treated as <code>expr IS NULL</code> , that is, they return true if <code>expr</code> evaluates to the null value, and false otherwise. The correct SQL-spec-compliant behavior of <code>expr = NULL</code> is to always return null (unknown).	master session reload
unix_socket_directory	directory path	unset	Specifies the directory of the UNIX-domain socket on which the server is to listen for connections from client applications.	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
unix_socket_group	UNIX group name	unset	Sets the owning group of the UNIX-domain socket. By default this is an empty string, which uses the default group for the current user.	local system restart
unix_socket_permissions	numeric UNIX file permission mode (as accepted by the <i>chmod</i> or <i>umask</i> commands)	511	Sets the access permissions of the UNIX-domain socket. UNIX-domain sockets use the usual UNIX file system permission set. Note that for a UNIX-domain socket, only write permission matters.	local system restart
update_process_title	Boolean	on	Enables updating of the process title every time a new SQL command is received by the server. The process title is typically viewed by the <i>ps</i> command.	local system restart
vacuum_cost_delay	milliseconds < 0 (in multiples of 10)	0	The length of time that the process will sleep when the cost limit has been exceeded. 0 disables the cost-based vacuum delay feature.	local system restart
vacuum_cost_limit	integer > 0	200	The accumulated cost that will cause the vacuuming process to sleep.	local system restart
vacuum_cost_page_dirty	integer > 0	20	The estimated cost charged when vacuum modifies a block that was previously clean. It represents the extra I/O required to flush the dirty block out to disk again.	local system restart
vacuum_cost_page_hit	integer > 0	1	The estimated cost for vacuuming a buffer found in the shared buffer cache. It represents the cost to lock the buffer pool, lookup the shared hash table and scan the content of the page.	local system restart
vacuum_cost_page_miss	integer > 0	10	The estimated cost for vacuuming a buffer that has to be read from disk. This represents the effort to lock the buffer pool, lookup the shared hash table, read the desired block in from the disk and scan its content.	local system restart
vacuum_freeze_min_age	integer 0-1000000000 00	10000000 0	Specifies the cutoff age (in transactions) that VACUUM should use to decide whether to replace transaction IDs with <i>FrozenXID</i> while scanning a table. For information about VACUUM and transaction ID management, see the <i>Greenplum Database System Administrator Guide</i> and the <a href="#">PostgreSQL documentation</a> .	local system restart

**Table 8.2** Server Configuration Parameters

Parameter	Value Range	Default	Description	Set Classifications
wal_receiver_status_interval	integer 0- INT_MAX/100 0	10 sec	For Greenplum Database master mirroring, sets the interval in seconds between walreceiver process status messages that are sent to the active master. Under heavy loads, the time might be longer.  The value of <a href="#">replication_timeout</a> controls the time that the walsender process waits for a walreceiver message.	master system reload superuser
xid_stop_limit	integer 10000000 - 2000000000	10000000 00	The number of transaction IDs prior to the ID where transaction ID wraparound occurs. When this limit is reached, Greenplum Database stops creating new transactions to avoid data loss due to transaction ID wraparound.	local system restart
xid_warn_limit	integer 10000000 - 2000000000	50000000 0	The number of transaction IDs prior to the limit specified by <a href="#">xid_stop_limit</a> . When Greenplum Database reaches this limit, it issues a warning to perform a VACUUM operation to avoid data loss due to transaction ID wraparound.	local system restart

## 9. Greenplum MapReduce Specification

This specification describes the document format and schema for defining Greenplum MapReduce jobs.

[MapReduce](#) is a programming model developed by Google for processing and generating large data sets on an array of commodity servers. Greenplum MapReduce allows programmers who are familiar with the MapReduce model to write map and reduce functions and submit them to the Greenplum Database parallel engine for processing.

To enable Greenplum to process MapReduce functions, the define the functions in a document, then pass the document to the Greenplum MapReduce program, `gpmapproduce`, for execution by the Greenplum Database parallel engine. The Greenplum Database system distributes the input data, executes the program across a set of machines, handles machine failures, and manages the required inter-machine communication.

See the *Greenplum Database Utility Guide* for information about `gpmapproduce`.

---

### Greenplum MapReduce Document Format

This section explains some basics of the Greenplum MapReduce document format to help you get started creating your own Greenplum MapReduce documents. Greenplum uses the [YAML 1.1](#) document format and then implements its own schema for defining the various steps of a MapReduce job.

All Greenplum MapReduce files must first declare the version of the YAML specification they are using. After that, three dashes (---) denote the start of a document, and three dots (...) indicate the end of a document without starting a new one. Comment lines are prefixed with a pound symbol (#). It is possible to declare multiple Greenplum MapReduce documents in the same file:

```
%YAML 1.1
---
# Begin Document 1
# ...
---
# Begin Document 2
# ...
```

Within a Greenplum MapReduce document, there are three basic types of data structures or *nodes*: *scalars*, *sequences* and *mappings*.

A *scalar* is a basic string of text indented by a space. If you have a scalar input that spans multiple lines, a preceding pipe ( | ) denotes a *literal* style, where all line breaks are significant. Alternatively, a preceding angle bracket ( > ) folds a single line break to a space for subsequent lines that have the same indentation level. If a string contains characters that have reserved meaning, the string must be quoted or the special character must be escaped with a backslash ( \ ).

```
# Read each new line literally
somekey: |
    this value contains two lines
    and each line is read literally
# Treat each new line as a space
anotherkey: >
    this value contains two lines
    but is treated as one continuous line
# This quoted string contains a special character
ThirdKey: "This is a string: not a mapping"
```

A *sequence* is a list with each entry in the list on its own line denoted by a dash and a space ( - ). Alternatively, you can specify an inline sequence as a comma-separated list within square brackets. A sequence provides a set of data and gives it an order. When you load a list into the Greenplum MapReduce program, the order is kept.

```
# list sequence
- this
- is
- a list
- with
- five scalar values
# inline sequence
[this, is, a list, with, five scalar values]
```

A *mapping* is used to pair up data values with identifiers called *keys*. Mappings use a colon and space ( : ) for each key: value pair, or can also be specified inline as a comma-separated list within curly braces. The *key* is used as an index for retrieving data from a mapping.

```
# a mapping of items
title: War and Peace
author: Leo Tolstoy
date: 1865

# same mapping written inline
{title: War and Peace, author: Leo Tolstoy, date: 1865}
```

Keys are used to associate meta information with each node and specify the expected node type (*scalar*, *sequence* or *mapping*). See “[Greenplum MapReduce Document Schema](#)” on page 515 for the keys expected by the Greenplum MapReduce program.

The Greenplum MapReduce program processes the nodes of a document in order and uses indentation (spaces) to determine the document hierarchy and the relationships of the nodes to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

## Greenplum MapReduce Document Schema

Greenplum MapReduce uses the YAML document framework and implements its own YAML schema. The basic structure of a Greenplum MapReduce document is:

```
%YAML 1.1
---
VERSION: 1.0.0.2
DATABASE: dbname
USER: db_username
HOST: master_hostname
PORT: master_port

DEFINE:

- INPUT:
  NAME: input_name
  FILE:
    - hostname:/path/to/file
  GPFDIST:
    - hostname:port/file_pattern
  TABLE: table_name
  QUERY: SELECT_statement
  EXEC: command_string
  COLUMNS:
    - field_name data_type
  FORMAT: TEXT | CSV
  DELIMITER: delimiter_character
  ESCAPE: escape_character
  NULL: null_string
  QUOTE: csv_quote_character
  ERROR_LIMIT: integer
  ENCODING: database_encoding
```

```

- OUTPUT:
  NAME: output_name
  FILE: file_path_on_client
  TABLE: table_name
  KEYS:
    - column_name
  MODE: REPLACE | APPEND

- MAP:
  NAME: function_name
  FUNCTION: function_definition
  LANGUAGE: perl | python | c
  LIBRARY: /path/filename.so
  PARAMETERS:
    - name type
  RETURNS:
    - name type
  OPTIMIZE: STRICT IMMUTABLE
  MODE: SINGLE | MULTI

- TRANSITION | CONSOLIDATE | FINALIZE:
  NAME: function_name
  FUNCTION: function_definition
  LANGUAGE: perl | python | c
  LIBRARY: /path/filename.so
  PARAMETERS:
    - name type
  RETURNS:
    - name type
  OPTIMIZE: STRICT IMMUTABLE
  MODE: SINGLE | MULTI

```

```

- REDUCE:
  NAME: reduce_job_name
  TRANSITION: transition_function_name
  CONSOLIDATE: consolidate_function_name
  FINALIZE: finalize_function_name
  INITIALIZE: value
  KEYS:
    - key_name

- TASK:
  NAME: task_name
  SOURCE: input_name
  MAP: map_function_name
  REDUCE: reduce_function_name

EXECUTE:

- RUN:
  SOURCE: input_or_task_name
  TARGET: output_name
  MAP: map_function_name
  REDUCE: reduce_function_name

...

```

**VERSION**

Required. The version of the Greenplum MapReduce YAML specification. Current versions are 1.0.0.1.

**DATABASE**

Optional. Specifies which database in Greenplum to connect to. If not specified, defaults to the default database or `$PGDATABASE` if set.

**USER**

Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or `$PGUSER` if set. You must be a Greenplum superuser to run functions written in untrusted Python and Perl. Regular database users can run functions written in trusted Perl. You also must be a database superuser to run MapReduce jobs that contain [FILE](#), [GPFDIST](#) or [EXEC](#) input types.

**HOST**

Optional. Specifies Greenplum master host name. If not specified, defaults to localhost or `$PGHOST` if set.

**PORT**

Optional. Specifies Greenplum master port. If not specified, defaults to 5432 or `$PGPORT` if set.

**DEFINE**

Required. A sequence of definitions for this MapReduce document. The **DEFINE** section must have at least one **INPUT** definition.

**INPUT**

Required. Defines the input data. Every MapReduce document must have at least one input defined. Multiple input definitions are allowed in a document, but each input definition can specify only one of these access types: a file, a `gpfdist` file distribution program, a table in the database, an SQL command, or an operating system command. See the *Greenplum Database Utility Guide* for information about `gpfdist`.

**NAME**

A name for this input. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**FILE**

A sequence of one or more input files in the format: `seghostname[:port]/path/to/filename`. You must be a Greenplum Database superuser to run MapReduce jobs with **FILE** input. The file must reside on a Greenplum segment host.

**GPFDIST**

A sequence of one or more running `gpfdist` file distribution programs in the format: `hostname[:port]/file_pattern`. You must be a Greenplum Database superuser to run MapReduce jobs with **GPFDIST** input, unless the server configuration parameter `gp_external_grant_privileges` is set to on.

**TABLE**

The name of an existing table in the database.

**QUERY**

An SQL `SELECT` command to run within the database.

**EXEC**

An operating system command to run on the Greenplum segment hosts. The command is run by all segment instances in the system by default. For example, if you have four segment instances per segment host, the command will be run four times on each host. You must be a Greenplum Database superuser to run MapReduce jobs with **EXEC** input and the server configuration parameter `gp_external_enable_exec` is set to on.

**COLUMNS**

Optional. Columns are specified as: `column_name [data_type]`. If not specified, the default is `value text`. The **DELIMITER** character is what separates two data value fields (columns). A row is determined by a line feed character (0x0a).

**FORMAT**

Optional. Specifies the format of the data - either delimited text (**TEXT**) or comma separated values (**CSV**) format. If the data format is not specified, defaults to **TEXT**.

**DELIMITER**

Optional for **FILE**, **GPFDIST** and **EXEC** inputs. Specifies a single character that separates data values. The default is a tab character in **TEXT** mode, a comma in **CSV** mode. The delimiter character must only appear between any two data value fields. Do not place a delimiter at the beginning or end of a row.

**ESCAPE**

Optional for **FILE**, **GPFDIST** and **EXEC** inputs. Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to disable escaping by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

**NULL**

Optional for **FILE**, **GPFDIST** and **EXEC** inputs. Specifies the string that represents a null value. The default is `\N` in **TEXT** format, and an empty value with no quotations in **CSV** format. You might prefer an empty string even in **TEXT** mode for cases where you do not want to distinguish nulls from empty strings. Any input data item that matches this string will be considered a null value.

**QUOTE**

Optional for [FILE](#), [GPFDIST](#) and [EXEC](#) inputs. Specifies the quotation character for CSV formatted files. The default is a double quote ("). In CSV formatted files, data value fields must be enclosed in double quotes if they contain any commas or embedded new lines. Fields that contain double quote characters must be surrounded by double quotes, and the embedded double quotes must each be represented by a pair of consecutive double quotes. It is important to always open and close quotes correctly in order for data rows to be parsed correctly.

**ERROR\_LIMIT**

If the input rows have format errors they will be discarded provided that the error limit count is not reached on any Greenplum segment instance during input processing. If the error limit is not reached, all good rows will be processed and any error rows discarded.

**ENCODING**

Character set encoding to use for the data. Specify a string constant (such as 'SQL\_ASCII'), an integer encoding number, or DEFAULT to use the default client encoding. See [“Character Set Support”](#) for more information.

**OUTPUT**

Optional. Defines where to output the formatted data of this MapReduce job. If output is not defined, the default is STDOUT (standard output of the client). You can send output to a file on the client host or to an existing table in the database.

**NAME**

A name for this output. The default output name is STDOUT. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and input names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**FILE**

Specifies a file location on the MapReduce client machine to output data in the format: */path/to/filename*

**TABLE**

Specifies the name of a table in the database to output data. If this table does not exist prior to running the MapReduce job, it will be created using the distribution policy specified with [KEYS](#).

**KEYS**

Optional for [TABLE](#) output. Specifies the column(s) to use as the Greenplum Database distribution key. If the [EXECUTE](#) task contains a [REDUCE](#) definition, then the REDUCE keys will be used as the table distribution key by default. Otherwise, the first column of the table will be used as the distribution key.

**MODE**

Optional for [TABLE](#) output. If not specified, the default is to create the table if it does not already exist, but error out if it does exist. Declaring [APPEND](#) adds output data to an existing table (provided the table schema matches the output format) without removing any existing data. Declaring [REPLACE](#) will drop the table if it exists and then recreate it. Both [APPEND](#) and [REPLACE](#) will create a new table if one does not exist.

**MAP**

Required. Each [MAP](#) function takes data structured in *(key, value)* pairs, processes each pair, and generates zero or more output *(key, value)* pairs. The Greenplum MapReduce framework then collects all pairs with the same key from all output lists and groups them together. This output is then passed to the [REDUCE](#) task, which is comprised of [TRANSITION](#) | [CONSOLIDATE](#) | [FINALIZE](#) functions. There is one predefined [MAP](#) function named [IDENTITY](#) that returns *(key, value)* pairs unchanged. Although *(key, value)* are the default parameters, you can specify other prototypes as needed.

**TRANSITION | CONSOLIDATE | FINALIZE**

[TRANSITION](#), [CONSOLIDATE](#) and [FINALIZE](#) are all component pieces of [REDUCE](#). A [TRANSITION](#) function is required. [CONSOLIDATE](#) and [FINALIZE](#) functions are optional. By default, all take *state* as the first of their input [PARAMETERS](#), but other prototypes can be defined as well.

A [TRANSITION](#) function iterates through each value of a given key and accumulates values in a *state* variable. When the transition function is called on the first value of a key, the *state* is set to the value specified by [INITIALIZE](#) of a [REDUCE](#) job (or the default state value for the data type). A transition takes two arguments as input; the current state of the key reduction, and the next value, which then produces a new *state*.

If a [CONSOLIDATE](#) function is specified, [TRANSITION](#) processing is performed at the segment-level before redistributing the keys across the Greenplum interconnect for final aggregation (two-phase aggregation). Only the resulting *state* value for a given key is redistributed, resulting in lower interconnect traffic and greater parallelism. [CONSOLIDATE](#) is handled like a [TRANSITION](#), except that instead of *(state + value) => state*, it is *(state + state) => state*.

If a [FINALIZE](#) function is specified, it takes the final *state* produced by [CONSOLIDATE](#) (if present) or [TRANSITION](#) and does any final processing before emitting the final result. [TRANSITION](#) and [CONSOLIDATE](#) functions cannot return a set of values. If you need a [REDUCE](#) job to return a set, then a [FINALIZE](#) is necessary to transform the final state into a set of output values.

**NAME**

Required. A name for the function. Names must be unique with regards to the names of other objects in this MapReduce job (such as function, task, input and output names). You can also specify the name of a function built-in to Greenplum Database. If using a built-in function, do not supply [LANGUAGE](#) or a [FUNCTION](#) body.

**FUNCTION**

Optional. Specifies the full body of the function using the specified [LANGUAGE](#). If [FUNCTION](#) is not specified, then a built-in database function corresponding to [NAME](#) is used.

**LANGUAGE**

Required when [FUNCTION](#) is used. Specifies the implementation language used to interpret the function. This release has language support for perl, python, and C. If calling a built-in database function, [LANGUAGE](#) should not be specified.

**LIBRARY**

Required when [LANGUAGE](#) is C (not allowed for other language functions). To use this attribute, [VERSION](#) must be 1.0.0.2. The specified library file must be installed prior to running the MapReduce job, and it must exist in the same file system location on all Greenplum hosts (master and segments).

**PARAMETERS**

Optional. Function input parameters. The default type is text.

MAP default - key text, value text

TRANSITION default - state text, value text

CONSOLIDATE default - state1 text, state2 text (must have exactly two input parameters of the same data type)

FINALIZE default - state text (single parameter only)

**RETURNS**

Optional. The default return type is text.

MAP default - key text, value text

TRANSITION default - state text (single return value only)

CONSOLIDATE default - state text (single return value only)

FINALIZE default - value text

**OPTIMIZE**

Optional optimization parameters for the function:

STRICT - function is not affected by NULL values

**IMMUTABLE** - function will always return the same value for a given input

### **MODE**

Optional. Specifies the number of rows returned by the function.

**MULTI** - returns 0 or more rows per input record. The return value of the function must be an array of rows to return, or the function must be written as an iterator using `yield` in Python or `return_next` in Perl. **MULTI** is the default mode for **MAP** and **FINALIZE** functions.

**SINGLE** - returns exactly one row per input record. **SINGLE** is the only mode supported for **TRANSITION** and **CONSOLIDATE** functions. When used with **MAP** and **FINALIZE** functions, **SINGLE** mode can provide modest performance improvement.

### **REDUCE**

Required. A **REDUCE** definition names the **TRANSITION** | **CONSOLIDATE** | **FINALIZE** functions that comprise the reduction of (key, value) pairs to the final result set. There are also several predefined **REDUCE** jobs you can execute, which all operate over a column named `value`:

**IDENTITY** - returns (key, value) pairs unchanged

**SUM** - calculates the sum of numeric data

**AVG** - calculates the average of numeric data

**COUNT** - calculates the count of input data

**MIN** - calculates minimum value of numeric data

**MAX** - calculates maximum value of numeric data

### **NAME**

Required. The name of this **REDUCE** job. Names must be unique with regards to the names of other objects in this MapReduce job (function, task, input and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

### **TRANSITION**

Required. The name of the **TRANSITION** function.

### **CONSOLIDATE**

Optional. The name of the **CONSOLIDATE** function.

### **FINALIZE**

Optional. The name of the **FINALIZE** function.

**INITIALIZE**

Optional for `text` and `float` data types. Required for all other data types. The default value for text is `' '`. The default value for float is `0.0`. Sets the initial `state` value of the `TRANSITION` function.

**KEYS**

Optional. Defaults to `[key, *]`. When using a multi-column reduce it may be necessary to specify which columns are key columns and which columns are value columns. By default, any input columns that are not passed to the `TRANSITION` function are key columns, and a column named `key` is always a key column even if it is passed to the `TRANSITION` function. The special indicator `*` indicates all columns not passed to the `TRANSITION` function. If this indicator is not present in the list of keys then any unmatched columns are discarded.

**TASK**

Optional. A `TASK` defines a complete end-to-end `INPUT/MAP/REDUCE` stage within a Greenplum MapReduce job pipeline. It is similar to `EXECUTE` except it is not immediately executed. A task object can be called as `INPUT` to further processing stages.

**NAME**

Required. The name of this task. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, reduce function, input and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**SOURCE**

The name of an `INPUT` or another `TASK`.

**MAP**

Optional. The name of a `MAP` function. If not specified, defaults to `IDENTITY`.

**REDUCE**

Optional. The name of a `REDUCE` function. If not specified, defaults to `IDENTITY`.

**EXECUTE**

Required. `EXECUTE` defines the final `INPUT/MAP/REDUCE` stage within a Greenplum MapReduce job pipeline.

**RUN****SOURCE**

Required. The name of an `INPUT` or `TASK`.

**TARGET**

Optional. The name of an [OUTPUT](#). The default output is `STDOUT`.

**MAP**

Optional. The name of a [MAP](#) function. If not specified, defaults to `IDENTITY`.

**REDUCE**

Optional. The name of a [REDUCE](#) function. Defaults to `IDENTITY`.

## Example Greenplum MapReduce Document

```
# This example MapReduce job processes documents and looks for keywords in them.
# It takes two database tables as input:
#   - documents (doc_id integer, url text, data text)
#   - keywords  (keyword_id integer, keyword text)#
# The documents data is searched for occurrences of keywords and returns results of
# url, data and keyword (a keyword can be multiple words, such as "high performance
# computing")

%YAML 1.1
---

VERSION: 1.0.0.1
# Connect to Greenplum Database using this database and role
DATABASE: webdata
USER: jsmith
# Begin definition section
DEFINE:

  # Declare the input, which selects all columns and rows from the
  # 'documents' and 'keywords' tables.

  - INPUT:
      NAME: doc
      TABLE: documents

  - INPUT:
      NAME: kw
      TABLE: keywords

# Define the map functions to extract terms from documents and keyword
# This example simply splits on white space, but it would be possible
# to make use of a python library like nltk (the natural language toolkit)
# to perform more complex tokenization and word stemming.
```

```

- MAP:

NAME:      doc_map
LANGUAGE:  python
FUNCTION:  |

    i = 0                # the index of a word within the document
    terms = {}           # a hash of terms and their indexes within the document
    # Lower-case and split the text string on space
    for term in data.lower().split():
        i = i + 1        # increment i (the index)
    # Check for the term in the terms list:
    # if stem word already exists, append the i value to the array entry
    # corresponding to the term. This counts multiple occurrences of the word.
    # If stem word does not exist, add it to the dictionary with position i.
    # For example:
    #   data: "a computer is a machine that manipulates data"
    #   "a" [1, 4]
    #   "computer" [2]
    #   "machine" [3]
    #   ...
    if term in terms:
        terms[term] += ',' + str(i)
    else:
        terms[term] = str(i)
    # Return multiple lines for each document. Each line consists of
    # the doc_id, a term and the positions in the data where the term appeared.
    # For example:
    #   (doc_id => 100, term => "a", [1,4]
    #   (doc_id => 100, term => "computer", [2]
    #   ...
    for term in terms:
        yield([doc_id, term, terms[term]])

OPTIMIZE:  STRICT IMMUTABLE

PARAMETERS:

    - doc_id integer
    - data text

RETURNS:

    - doc_id integer
    - term text
    - positions text

```

```

# The map function for keywords is almost identical to the one for documents
# but it also counts of the number of terms in the keyword.

- MAP:

        - positions text

# A TASK is an object that defines an entire INPUT/MAP/REDUCE stage
# within a Greenplum MapReduce pipeline. It is like EXECUTION, but it is
# executed only when called as input to other processing stages.
# Identify a task called 'doc_prep' which takes in the 'doc' INPUT defined earlier
# and runs the 'doc_map' MAP function which returns doc_id, term, [term_position]

- TASK:

    NAME: doc_prep
    SOURCE: doc
    MAP: doc_map

```

```

# Identify a task called 'kw_prep' which takes in the 'kw' INPUT defined earlier
# and runs the kw_map MAP function which returns kw_id, term, [term_position]

- TASK:

    NAME: kw_prep

    SOURCE: kw

    MAP: kw_map

# One advantage of Greenplum MapReduce is that MapReduce tasks can be
# used as input to SQL operations and SQL can be used to process a MapReduce task.
# This INPUT defines a SQL query that joins the output of the 'doc_prep'
# TASK to that of the 'kw_prep' TASK. Matching terms are output to the 'candidate'
# list (any keyword that shares at least one term with the document).

- INPUT:

    NAME: term_join

    QUERY: |

        SELECT doc.doc_id, kw.keyword_id, kw.term, kw.nterms,
               doc.positions as doc_positions,
               kw.positions as kw_positions
        FROM doc_prep doc INNER JOIN kw_prep kw ON (doc.term = kw.term)

# In Greenplum MapReduce, a REDUCE function is comprised of one or more functions.
# A REDUCE has an initial 'state' variable defined for each grouping key. that is
# A TRANSITION function adjusts the state for every value in a key grouping.
# If present, an optional CONSOLIDATE function combines multiple
# 'state' variables. This allows the TRANSITION function to be executed locally at
# the segment-level and only redistribute the accumulated 'state' over
# the network. If present, an optional FINALIZE function can be used to perform
# final computation on a state and emit one or more rows of output from the state.
#
# This REDUCE function is called 'term_reducer' with a TRANSITION function
# called 'term_transition' and a FINALIZE function called 'term_finalizer'

- REDUCE:

    NAME: term_reducer

    TRANSITION: term_transition

    FINALIZE: term_finalizer

```

**- TRANSITION:****NAME:** `term_transition`**LANGUAGE:** `python`**PARAMETERS:**

- `state` `text`
- `term` `text`
- `nterms` `integer`
- `doc_positions` `text`
- `kw_positions` `text`

**FUNCTION:** |

```

# 'state' has an initial value of '' and is a colon delimited set
# of keyword positions. keyword positions are comma delimited sets of
# integers. For example, '1,3,2:4:'
# If there is an existing state, split it into the set of keyword positions
# otherwise construct a set of 'nterms' keyword positions - all empty
if state:
    kw_split = state.split(':')
else:
    kw_split = []
    for i in range(0,nterms):
        kw_split.append('')
# 'kw_positions' is a comma delimited field of integers indicating what
# position a single term occurs within a given keyword.
# Splitting based on ',' converts the string into a python list.
# add doc_positions for the current term
for kw_p in kw_positions.split(','):
    kw_split[int(kw_p)-1] = doc_positions
# This section takes each element in the 'kw_split' array and strings
# them together placing a ':' in between each element from the array.
# For example: for the keyword "computer software computer hardware",
# the 'kw_split' array matched up to the document data of
# "in the business of computer software software engineers"
# would look like: ['5', '6,7', '5', '']
# and the outstate would look like: 5:6,7:5:
outstate = kw_split[0]
for s in kw_split[1:]:
    outstate = outstate + ':' + s
return outstate

```

```

- FINALIZE:

NAME: term_finalizer

LANGUAGE: python

RETURNS:

    - count integer

MODE: MULTI

FUNCTION: |

    if not state:
        return 0

    kw_split = state.split(':')

    # This function does the following:
    # 1) Splits 'kw_split' on ':'
    #    for example, 1,5,7:2,8 creates '1,5,7' and '2,8'
    # 2) For each group of positions in 'kw_split', splits the set on ','
    #    to create ['1','5','7'] from Set 0: 1,5,7 and
    #    eventually ['2', '8'] from Set 1: 2,8
    # 3) Checks for empty strings
    # 4) Adjusts the split sets by subtracting the position of the set
    #    in the 'kw_split' array
    #    ['1','5','7'] - 0 from each element = ['1','5','7']
    #    ['2', '8'] - 1 from each element = ['1', '7']
    # 5) Resulting arrays after subtracting the offset in step 4 are
    #    intersected and their overlapping values kept:
    #    ['1','5','7'].intersect(['1', '7']) = [1,7]
    # 6) Determines the length of the intersection, which is the number of
    #    times that an entire keyword (with all its pieces) matches in the
    #    document data.

    previous = None

```

## MapReduce Flow Diagram

The following diagram shows the job flow of the MapReduce job defined in the example:

# 10. Greenplum PostGIS Extension

- [About PostGIS](#)
- [Greenplum PostGIS Extension](#)
- [Enabling PostGIS Support](#)
- [Migrating from PostGIS 1.4 to 2.0](#)
- [Usage](#)

---

## About PostGIS

PostGIS is a spatial database extension for PostgreSQL that allows GIS (Geographic Information Systems) objects to be stored in the database. PostGIS includes support for GiST-based R-Tree spatial indexes and functions for analysis and processing of GIS objects.

Go to <http://postgis.refractions.net/> for more information.

---

## Greenplum PostGIS Extension

The Greenplum PostGIS extension is available from the [EMC Download Center](#). You can install it using the Greenplum Package Manager (gppkg). For details, see gppkg in the *Greenplum Database Utility Guide*.

- Greenplum Database 4.3 supports PostGIS extension package version 2.0 (PostGIS 2.0.3).
- Greenplum Database 4.2.6 and later supports PostGIS extension package version 1.0 and 2.0 (PostGIS 1.4 and 2.0.3)  
Only one version of the PostGIS extension package, either 1.0 or 2.0, can be installed on an installation of Greenplum Database.
- Greenplum Database prior to 4.2.6 supports PostGIS extension package version 1.0 (PostGIS 1.4).

**Table 10.1** PostGIS Component Version

PostGIS Extension Package	PostGIS	Geos	Proj
2.0	2.0.3	3.3.8	4.8.0
1.0	1.4.2	3.2.2.	4.7.0

For the information about supported extension packages and software versions see the *Greenplum Database Release Notes*.

Major enhancements and changes in 2.0.3 from 1.4.2 include:

- Support for geographic coordinates (latitude and longitude) with a GEOGRAPHY type and related functions.
- Input format support for these formats: GML, KML, and JSON
- Unknown SRID changed from -1 to 0
- 3D relationship and measurement support functions
- Making spatial indexes 3D aware
- KNN GiST centroid distance operator
- Many deprecated functions are removed
- Performance improvements

See the PostGIS documentation for a list of changes.

[http://postgis.net/docs/manual-2.0/release\\_notes.html](http://postgis.net/docs/manual-2.0/release_notes.html)

**Warning:** PostGIS 2.0 removed many functions that were deprecated but available in PostGIS 1.4. Functions and applications written with functions that were deprecated in PostGIS 1.4 might need to be rewritten. See the PostGIS documentation for a list of new, enhanced, or changed functions.

[http://postgis.net/docs/manual-2.0/PostGIS\\_Special\\_Functions\\_Index.html#NewFunctions](http://postgis.net/docs/manual-2.0/PostGIS_Special_Functions_Index.html#NewFunctions)

---

## Greenplum PostGIS Limitations

The Greenplum PostGIS extension does not support the following features:

- `estimated_extent` functions
- PostGIS long transaction support
- Topology
- Raster
- Geometry and geography type modifier

---

## Enabling PostGIS Support

After installing the PostGIS extension package, you enable PostGIS support for each database that requires its use. To enable the support, run enabler SQL scripts that are supplied with the PostGIS package, in your target database.

For PostGIS 1.4 the enabler script `postgis.sql`

```
psql -f postgis.sql -d your_database
```

Your database is now spatially enabled.

For PostGIS 2.0.3, you run two SQL scripts `postgis.sql` and `spatial_ref_sys.sql` in your target database.

For example:

```
psql -d mydatabase -f
```

```
$GPHOME/share/postgresql/contrib/postgis-2.0/postgis.sql
psql -d mydatabase -f
$GPHOME/share/postgresql/contrib/postgis-2.0/spatial_ref_sys.sql
```

**Note:** `spatial_ref_sys.sql` populates the `spatial_ref_sys` table with EPSG coordinate system definition identifiers. If you have overridden standard entries and want to use those overrides, do not load the `spatial_ref_sys.sql` file when creating the new database.

Your database is now spatially enabled.

---

## Migrating from PostGIS 1.4 to 2.0

To migrate a PostGIS-enabled database from 1.4 to 2.0 you must perform a PostGIS HARD UPGRADE. A HARD UPGRADE consists of dumping a database that is enabled with PostGIS 1.4 and loading the database the data to a new database that is enabled with PostGIS 2.0.

For information about a PostGIS HARD UPGRADE procedure, see the PostGIS documentation:

[http://postgis.net/docs/manual-2.0/postgis\\_installation.html#hard\\_upgrade](http://postgis.net/docs/manual-2.0/postgis_installation.html#hard_upgrade)

---

## Usage

The following example SQL statements create non-OpenGIS tables and geometries.

```
CREATE TABLE geom_test ( gid int4, geom geometry,
                          name varchar(25) );
INSERT INTO geom_test ( gid, geom, name )
VALUES ( 1, 'POLYGON((0 0 0,0 5 0,5 5 0,5 0 0,0 0 0))',
        '3D Square');
INSERT INTO geom_test ( gid, geom, name )
VALUES ( 2, 'LINESTRING(1 1 1,5 5 5,7 7 5)', '3D Line' );
INSERT INTO geom_test ( gid, geom, name )
VALUES ( 3, 'MULTIPOINT(3 4,8 9)', '2D Aggregate Point' );

SELECT * from geom_test WHERE geom &&
Box3D(ST_GeomFromEWKT('LINESTRING(2 2 0, 3 3 0)'));
```

The following example SQL statements create a table, adds a geometry column to the table with a SRID integer value that references an entry in the SPATIAL\_REF\_SYS table. The INSERT statements add to geopoints to the table.

```
CREATE TABLE geotest (id INT4, name VARCHAR(32) );
SELECT AddGeometryColumn('geotest','geopoint',
                          4326,'POINT',2);
INSERT INTO geotest (id, name, geopoint)
```

```
VALUES (1, 'Olympia',
        ST_GeometryFromText('POINT(-122.90 46.97)', 4326));
INSERT INTO geotest (id, name, geopoint) |
VALUES (2, 'Renton',
        ST_GeometryFromText('POINT(-122.22 47.50)', 4326));

SELECT name, ST_AsText(geopoint) FROM geotest;
```

---

## Spatial Indexes

PostgreSQL provides support for GiST spatial indexing. The GiST scheme offers indexing even on large objects. It uses a system of lossy indexing in which smaller objects act as proxies for larger ones in the index. In the PostGIS indexing system, all objects use their bounding boxes as proxies in the index.

### Building a Spatial Index

You can build a GiST index as follows:

```
CREATE INDEX indexname
ON tablename
USING GIST ( geometryfield );
```

# 11. Summary of Greenplum Features

This section provides a high-level overview of the system requirements and feature set of Greenplum Database. It contains the following topics:

- [Greenplum SQL Standard Conformance](#)
- [Greenplum and PostgreSQL Compatibility](#)

---

## Greenplum SQL Standard Conformance

The SQL language was first formally standardized in 1986 by the American National Standards Institute (ANSI) as SQL 1986. Subsequent versions of the SQL standard have been released by ANSI and as International Organization for Standardization (ISO) standards: SQL 1989, SQL 1992, SQL 1999, SQL 2003, SQL 2006, and finally SQL 2008, which is the current SQL standard. The official name of the standard is ISO/IEC 9075-14:2008. In general, each new version adds more features, although occasionally features are deprecated or removed.

It is important to note that there are no commercial database systems that are fully compliant with the SQL standard. Greenplum Database is almost fully compliant with the SQL 1992 standard, with most of the features from SQL 1999. Several features from SQL 2003 have also been implemented (most notably the SQL OLAP features).

This section addresses the important conformance issues of Greenplum Database as they relate to the SQL standards. For a feature-by-feature list of Greenplum's support of the latest SQL standard, see [“SQL 2008 Optional Feature Compliance”](#).

---

### Core SQL Conformance

In the process of building a parallel, shared-nothing database system and query optimizer, certain common SQL constructs are not currently implemented in Greenplum Database. The following SQL constructs are not supported:

1. Some set returning subqueries in `EXISTS` or `NOT EXISTS` clauses that Greenplum's parallel optimizer cannot rewrite into joins.
2. `UNION ALL` of joined tables with subqueries.
3. Set-returning functions in the `FROM` clause of a subquery.
4. Backwards scrolling cursors, including the use of `FETCH PRIOR`, `FETCH FIRST`, `FETCH ABOLUTE`, and `FETCH RELATIVE`.
5. In `CREATE TABLE` statements (on hash-distributed tables): a `UNIQUE` or `PRIMARY KEY` clause must include all of (or a superset of) the distribution key columns. Because of this restriction, only one `UNIQUE` clause or `PRIMARY KEY` clause is allowed in a `CREATE TABLE` statement. `UNIQUE` or `PRIMARY KEY` clauses are not allowed on randomly-distributed tables.

6. `CREATE UNIQUE INDEX` statements that do not contain all of (or a superset of) the distribution key columns. `CREATE UNIQUE INDEX` is not allowed on randomly-distributed tables.  
Note that `UNIQUE INDEXES` (but not `UNIQUE CONSTRAINTS`) are enforced on a part basis within a partitioned table. They guarantee the uniqueness of the key within each part or sub-part.
7. `VOLATILE` or `STABLE` functions cannot execute on the segments, and so are generally limited to being passed literal values as the arguments to their parameters.
8. Triggers are not supported since they typically rely on the use of `VOLATILE` functions.
9. Referential integrity constraints (foreign keys) are not enforced in Greenplum Database. Users can declare foreign keys and this information is kept in the system catalog, however.
10. Sequence manipulation functions `CURRVAL` and `LASTVAL`.
11. `DELETE WHERE CURRENT OF` and `UPDATE WHERE CURRENT OF` (positioned delete and positioned update operations).

---

## SQL 1992 Conformance

The following features of SQL 1992 are not supported in Greenplum Database:

1. `NATIONAL CHARACTER (NCHAR)` and `NATIONAL CHARACTER VARYING (NVARCHAR)`. Users can declare the `NCHAR` and `NVARCHAR` types, however they are just synonyms for `CHAR` and `VARCHAR` in Greenplum Database.
2. `CREATE ASSERTION` statement.
3. `INTERVAL` literals are supported in Greenplum Database, but do not conform to the standard.
4. `GET DIAGNOSTICS` statement.
5. `GRANT INSERT` or `UPDATE` privileges on columns. Privileges can only be granted on tables in Greenplum Database.
6. `GLOBAL TEMPORARY TABLES` and `LOCAL TEMPORARY TABLES`. Greenplum `TEMPORARY TABLES` do not conform to the SQL standard, but many commercial database systems have implemented temporary tables in the same way. Greenplum temporary tables are the same as `VOLATILE TABLES` in Teradata.
7. `UNIQUE` predicate.
8. `MATCH PARTIAL` for referential integrity checks (most likely will not be implemented in Greenplum Database).

---

## SQL 1999 Conformance

The following features of SQL 1999 are not supported in Greenplum Database:

1. Large Object data types: BLOB, CLOB, NCLOB. However, the BYTEA and TEXT columns can store very large amounts of data in Greenplum Database (hundreds of megabytes).
2. MODULE (SQL client modules).
3. CREATE PROCEDURE (SQL/PSM). This can be worked around in Greenplum Database by creating a FUNCTION that returns void, and invoking the function as follows:  

```
SELECT myfunc(args);
```
4. The PostgreSQL/Greenplum function definition language (PL/PGSQL) is a subset of Oracle's PL/SQL, rather than being compatible with the SQL/PSM function definition language. Greenplum Database also supports function definitions written in Python, Perl, Java, and R.
5. BIT and BIT VARYING data types (intentionally omitted). These were deprecated in SQL 2003, and replaced in SQL 2008.
6. Greenplum supports identifiers up to 63 characters long. The SQL standard requires support for identifiers up to 128 characters long.
7. Prepared transactions (PREPARE TRANSACTION, COMMIT PREPARED, ROLLBACK PREPARED). This also means Greenplum does not support XA Transactions (2 phase commit coordination of database transactions with external transactions).
8. CHARACTER SET option on the definition of CHAR() or VARCHAR() columns.
9. Specification of CHARACTERS or OCTETS (BYTES) on the length of a CHAR() or VARCHAR() column. For example, VARCHAR(15 CHARACTERS) or VARCHAR(15 OCTETS) or VARCHAR(15 BYTES).
10. CURRENT\_SCHEMA function.
11. CREATE DISTINCT TYPE statement. CREATE DOMAIN can be used as a work-around in Greenplum.
12. The *explicit table* construct.

---

## SQL 2003 Conformance

The following features of SQL 2003 are not supported in Greenplum Database:

1. MERGE statements.
2. IDENTITY columns and the associated GENERATED ALWAYS/GENERATED BY DEFAULT clause. The SERIAL or BIGSERIAL data types are very similar to INT or BIGINT GENERATED BY DEFAULT AS IDENTITY.

3. `MULTISET` modifiers on data types.
4. `ROW` data type.
5. Greenplum Database syntax for using sequences is non-standard. For example, `nextval('seq')` is used in Greenplum instead of the standard `NEXT VALUE FOR seq`.
6. `GENERATED ALWAYS AS` columns. Views can be used as a work-around.
7. The sample clause (`TABLESAMPLE`) on `SELECT` statements. The `random()` function can be used as a work-around to get random samples from tables.
8. `NULLS FIRST/NULLS LAST` clause on `SELECT` statements and subqueries (nulls are always last in Greenplum Database).
9. The *partitioned join tables* construct (`PARTITION BY` in a join).
10. `GRANT SELECT` privileges on columns. Privileges can only be granted on tables in Greenplum Database. Views can be used as a work-around.
11. For `CREATE TABLE x (LIKE(y))` statements, Greenplum does not support the `[INCLUDING|EXCLUDING] [DEFAULTS|CONSTRAINTS|INDEXES]` clauses.
12. Greenplum array data types are almost SQL standard compliant with some exceptions. Generally customers should not encounter any problems using them.

---

## SQL 2008 Conformance

The following features of SQL 2008 are not supported in Greenplum Database:

1. `BINARY` and `VARBINARY` data types. `BYTEA` can be used in place of `VARBINARY` in Greenplum Database.
2. `FETCH FIRST` or `FETCH NEXT` clause for `SELECT`, for example:  

```
SELECT id, name FROM tabl ORDER BY id OFFSET 20 ROWS FETCH
NEXT 10 ROWS ONLY;
```

 Greenplum has `LIMIT` and `LIMIT OFFSET` clauses instead.
3. The `ORDER BY` clause is ignored in views and subqueries unless a `LIMIT` clause is also used. This is intentional, as the Greenplum optimizer cannot determine when it is safe to avoid the sort, causing an unexpected performance impact for such `ORDER BY` clauses. To work around, you can specify a really large `LIMIT`. For example: `SELECT * FROM mytable ORDER BY 1 LIMIT 9999999999`
4. The *row subquery* construct is not supported.
5. `TRUNCATE TABLE` does not accept the `CONTINUE IDENTITY` and `RESTART IDENTITY` clauses.

## Greenplum and PostgreSQL Compatibility

Greenplum Database is based on PostgreSQL 8.2 with a few features added in from the 8.3 release. To support the distributed nature and typical workload of a Greenplum Database system, some SQL commands have been added or modified, and there are a few PostgreSQL features that are not supported. Greenplum has also added features not found in PostgreSQL, such as physical data distribution, parallel query optimization, external tables, resource queues for workload management and enhanced table partitioning. For full SQL syntax and references, see the “[SQL Command Reference](#)”.

**Table 11.1** SQL Support in Greenplum Database

SQL Command	Supported in Greenplum	Modifications, Limitations, Exceptions
ALTER AGGREGATE	YES	
ALTER CONVERSION	YES	
ALTER DATABASE	YES	
ALTER DOMAIN	YES	
ALTER FILESPACE	YES	Greenplum Database parallel tablespace feature - not in PostgreSQL 8.2.15.
ALTER FUNCTION	YES	
ALTER GROUP	YES	An alias for <a href="#">ALTER ROLE</a>
ALTER INDEX	YES	
ALTER LANGUAGE	YES	
ALTER OPERATOR	YES	
ALTER OPERATOR CLASS	NO	
ALTER RESOURCE QUEUE	YES	Greenplum Database workload management feature - not in PostgreSQL.
ALTER ROLE	YES	<b>Greenplum Database Clauses:</b> RESOURCE QUEUE <i>queue_name</i>   none
ALTER SCHEMA	YES	
ALTER SEQUENCE	YES	
ALTER TABLE	YES	<b>Unsupported Clauses / Options:</b> CLUSTER ON ENABLE/DISABLE TRIGGER  <b>Greenplum Database Clauses:</b> ADD   DROP   RENAME   SPLIT   EXCHANGE PARTITION   SET SUBPARTITION TEMPLATE   SET WITH (REORGANIZE=true   false)   SET DISTRIBUTED BY
ALTER TABLESPACE	YES	

**Table 11.1** SQL Support in Greenplum Database

SQL Command	Supported in Greenplum	Modifications, Limitations, Exceptions
ALTER TRIGGER	NO	
ALTER TYPE	YES	
ALTER USER	YES	An alias for <a href="#">ALTER ROLE</a>
ANALYZE	YES	
BEGIN	YES	
CHECKPOINT	YES	
CLOSE	YES	
CLUSTER	YES	
COMMENT	YES	
COMMIT	YES	
COMMIT PREPARED	NO	
COPY	YES	<b>Modified Clauses:</b> ESCAPE [ AS ] 'escape'   'OFF' <b>Greenplum Database Clauses:</b> [LOG ERRORS INTO <i>error_table</i> ] SEGMENT REJECT LIMIT <i>count</i> [ROWS PERCENT]
CREATE AGGREGATE	YES	<b>Unsupported Clauses / Options:</b> [ , SORTOP = <i>sort_operator</i> ] <b>Greenplum Database Clauses:</b> [ , PREFUNC = <i>prefunc</i> ] <b>Limitations:</b> The functions used to implement the aggregate must be IMMUTABLE functions.
CREATE CAST	YES	
CREATE CONSTRAINT TRIGGER	NO	
CREATE CONVERSION	YES	
CREATE DATABASE	YES	
CREATE DOMAIN	YES	
CREATE EXTERNAL TABLE	YES	Greenplum Database parallel ETL feature - not in PostgreSQL 8.2.15.
CREATE FILESPACE	YES	Greenplum Database parallel tablespace feature - not in PostgreSQL 8.2.15.

**Table 11.1** SQL Support in Greenplum Database

SQL Command	Supported in Greenplum	Modifications, Limitations, Exceptions
CREATE FUNCTION	YES	<b>Limitations:</b> Functions defined as <code>STABLE</code> or <code>VOLATILE</code> can be executed in Greenplum Database provided that they are executed on the master only. <code>STABLE</code> and <code>VOLATILE</code> functions cannot be used in statements that execute at the segment level.
CREATE GROUP	YES	An alias for <code>CREATE ROLE</code>
CREATE INDEX	YES	<b>Greenplum Database Clauses:</b> <code>USING bitmap</code> (bitmap indexes) <b>Limitations:</b> <code>UNIQUE</code> indexes are allowed only if they contain all of (or a superset of) the Greenplum distribution key columns. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions. <code>CONCURRENTLY</code> keyword not supported in Greenplum.
CREATE LANGUAGE	YES	
CREATE OPERATOR	YES	<b>Limitations:</b> The function used to implement the operator must be an <code>IMMUTABLE</code> function.
CREATE OPERATOR CLASS	NO	
CREATE OPERATOR FAMILY	NO	
CREATE RESOURCE QUEUE	YES	Greenplum Database workload management feature - not in PostgreSQL 8.2.15.
CREATE ROLE	YES	<b>Greenplum Database Clauses:</b> <code>RESOURCE QUEUE queue_name   none</code>
CREATE RULE	YES	
CREATE SCHEMA	YES	
CREATE SEQUENCE	YES	<b>Limitations:</b> <ul style="list-style-type: none"> <li>• The <code>lastval</code> and <code>currval</code> functions are not supported.</li> <li>• The <code>setval</code> function is only allowed in queries that do not operate on distributed data.</li> </ul>

**Table 11.1** SQL Support in Greenplum Database

SQL Command	Supported in Greenplum	Modifications, Limitations, Exceptions
CREATE TABLE	YES	<b>Unsupported Clauses / Options:</b> [GLOBAL   LOCAL] REFERENCES FOREIGN KEY [DEFERRABLE   NOT DEFERRABLE]  <b>Limited Clauses:</b> <ul style="list-style-type: none"> <li>UNIQUE or PRIMARY KEY constraints are only allowed on hash-distributed tables (DISTRIBUTED BY), and the constraint columns must be the same as or a superset of the distribution key columns of the table and must include all the distribution key columns of the partitioning key.</li> </ul> <b>Greenplum Database Clauses:</b> DISTRIBUTED BY (column, [ ... ] )   DISTRIBUTED RANDOMLY PARTITION BY type (column [, ...]) ( partition_specification, [...] ) WITH (appendonly=true [,compresslevel=value,blocksize=value] ) 
CREATE TABLE AS	YES	See <a href="#">CREATE TABLE</a>
CREATE TABLESPACE	NO	<b>Greenplum Database Clauses:</b> FILESPACE <i>filespace_name</i>
CREATE TRIGGER	NO	
CREATE TYPE	YES	<b>Limitations:</b> The functions used to implement a new base type must be IMMUTABLE functions.
CREATE USER	YES	An alias for <a href="#">CREATE ROLE</a>
CREATE VIEW	YES	
DEALLOCATE	YES	
DECLARE	YES	<b>Unsupported Clauses / Options:</b> SCROLL FOR UPDATE [ OF column [, ...] ]  <b>Limitations:</b> Cursors are non-updatable, and cannot be backward-scrolled. Forward scrolling is supported.
DELETE	YES	<b>Unsupported Clauses / Options:</b> RETURNING
DROP AGGREGATE	YES	
DROP CAST	YES	
DROP CONVERSION	YES	

**Table 11.1** SQL Support in Greenplum Database

SQL Command	Supported in Greenplum	Modifications, Limitations, Exceptions
DROP DATABASE	YES	
DROP DOMAIN	YES	
DROP EXTERNAL TABLE	YES	Greenplum Database parallel ETL feature - not in PostgreSQL 8.2.15.
DROP FILESPACE	YES	Greenplum Database parallel tablespace feature - not in PostgreSQL 8.2.15.
DROP FUNCTION	YES	
DROP GROUP	YES	An alias for <a href="#">DROP ROLE</a>
DROP INDEX	YES	
DROP LANGUAGE	YES	
DROP OPERATOR	YES	
DROP OPERATOR CLASS	NO	
DROP OWNED	NO	
DROP RESOURCE QUEUE	YES	Greenplum Database workload management feature - not in PostgreSQL 8.2.15.
DROP ROLE	YES	
DROP RULE	YES	
DROP SCHEMA	YES	
DROP SEQUENCE	YES	
DROP TABLE	YES	
DROP TABLESPACE	NO	
DROP TRIGGER	NO	
DROP TYPE	YES	
DROP USER	YES	An alias for <a href="#">DROP ROLE</a>
DROP VIEW	YES	
END	YES	
EXECUTE	YES	
EXPLAIN	YES	

**Table 11.1** SQL Support in Greenplum Database

SQL Command	Supported in Greenplum	Modifications, Limitations, Exceptions
FETCH	YES	<b>Unsupported Clauses / Options:</b> LAST PRIOR BACKWARD BACKWARD ALL  <b>Limitations:</b> Cannot fetch rows in a nonsequential fashion; backward scan is not supported.
GRANT	YES	
INSERT	YES	<b>Unsupported Clauses / Options:</b> RETURNING
LISTEN	NO	
LOAD	YES	
LOCK	YES	
MOVE	YES	See <a href="#">FETCH</a>
NOTIFY	NO	
PREPARE	YES	
PREPARE TRANSACTION	NO	
REASSIGN OWNED	YES	
REINDEX	YES	
RELEASE SAVEPOINT	YES	
RESET	YES	
REVOKE	YES	
ROLLBACK	YES	
ROLLBACK PREPARED	NO	
ROLLBACK TO SAVEPOINT	YES	
SAVEPOINT	YES	
SELECT	YES	<b>Limitations:</b> <ul style="list-style-type: none"> <li>Limited use of VOLATILE and STABLE functions in FROM or WHERE clauses</li> <li>Text search (Tsearch2) is not supported</li> <li>FETCH FIRST or FETCH NEXT clauses not supported</li> </ul> <b>Greenplum Database Clauses (OLAP):</b> [GROUP BY <i>grouping_element</i> [, ...]] [WINDOW <i>window_name</i> AS ( <i>window_specification</i> )] [FILTER ( <i>WHERE condition</i> )] applied to an aggregate function in the SELECT list

**Table 11.1** SQL Support in Greenplum Database

SQL Command	Supported in Greenplum	Modifications, Limitations, Exceptions
SELECT INTO	YES	See <a href="#">SELECT</a>
SET	YES	
SET CONSTRAINTS	NO	In PostgreSQL, this only applies to foreign key constraints, which are currently not enforced in Greenplum Database.
SET ROLE	YES	
SET SESSION AUTHORIZATION	YES	Deprecated as of PostgreSQL 8.1 - see <a href="#">SET ROLE</a>
SET TRANSACTION	YES	
SHOW	YES	
START TRANSACTION	YES	
TRUNCATE	YES	
UNLISTEN	NO	
UPDATE	YES	<b>Unsupported Clauses:</b> RETURNING  <b>Limitations:</b> <ul style="list-style-type: none"> <li>• SET not allowed for Greenplum distribution key columns.</li> </ul>
VACUUM	YES	<b>Limitations:</b> VACUUM FULL is not recommended in Greenplum Database.
VALUES	YES
